THE

# JOURNAL OF HORTICULTURE,

## COTTAGE GARDENER,

AND

## HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY

ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME XII. THIRD SERIES.

JANUARY — JUNE, 1886.

LONDON:

PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

---

1886.

LONDON:  
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,  
171, FLEET STREET.

## TO OUR READERS.

---

WHEN time passes quickly it is said to pass pleasantly. To ourselves the half-yearly volumes of the Journal appear to be completed in a very short period of time, and we doubt not it is the same with our experienced helpers.

It is pleasant to share in work that is appreciated, and we have the satisfaction of knowing that our efforts to gather and distribute information on subjects of culture meet with warm and wide acceptance.

Our volume closes as the great Rose season opens, and when these words reach our readers the Floral Queen of summer will have received the homage of thousands of loyal subjects. We join in that great throng, and shall not cease to hope for still finer Roses and firmer friendships.

Taking the Rose, for the moment, as the representative of floriculture, we cannot fail to observe how real is the interest that is invested in this branch of the greater subject of which the *Journal of Horticulture* is an exponent.

In the broadest sense it will continue to reflect the character of the horticultural industry, as it will, as heretofore, record the practice of expert craftsmen as the best means of pointing the way for the less experienced who are striving to win success.

The policy of the Journal remains the same. Unmoved by political or polemical strife it will be steadily, and, we trust, harmoniously pursued. Its mission is to do good, and the "vote and interest" of a world-wide constituency is sought on that ground, and that alone.

As there have been no abstentions from our poll we return thanks to all who have assisted in the completion of the volume to which the annexed index refers, in the full assurance that a still larger measure of support will be accorded in the future.

## INDEX.

-----+-----

- ABBERLEY HALL, 405  
 Abbey Park, Leicester, 399  
 Acacia platyptera, culture, 34  
 108  
 Acanthophippium bicolor, 233  
 Achimenes, 261  
 Adiantum, 97; cardiochloena,  
 182; cuneatum for market,  
 476  
 Aeschynanthus, 366  
 African vegetation, 25  
 Agathaea coelestis, 74  
 Agricultural returns—fruit  
 nurseries and market gar-  
 dens, 465  
 Allamanda nerifolia, 399  
 Alderminster, 401  
 Almond trees, 273  
 Alocasia, culture of, 120  
 Alternantheras, propagating,  
 201  
 Amaryllises—Belladonna, 142;  
 culture, 261; new, 293  
 Ammonia—in vineries, 311, 481;  
 in fruit and planthouses, 509;  
 520; in ferneries, 520  
 Anemones in spring, 252; ne-  
 morosa and alba, 335; appe-  
 nina, 404  
 Annuals for bedding, 201  
 Anthracite coal, 263  
 Anthuriums, culture of, 120;  
 Andreanum, large spathe of,  
 354; monographic list of, 443;  
 splendendum, 488  
 Ants, destroying, 283  
 Antwerp, notes at, 153  
 Apples—keeping, 2, 49, 93;  
 Bramley's Seedling, 67; the  
 Cobham, 70; insect enemies  
 of the, 71, 276, 418; the Sheep's  
 Nose, 142; budding, 242;  
 D'Arcy Spice, 273; Newland  
 Sack, 338; from the Antipodes,  
 373; King of the Pippins and  
 Golden Winter Pearmain, 454;  
 shoots dying, 520  
 Aquarium, Westminster, shows  
 at the Royal, 152  
 Aquilegias, 415  
 Arafias, 366; Chabrieri, 214  
 Araucaria imbricata coning, 499  
 Arctic region, vegetation of the,  
 293  
 Arisema fimbriatum, 113  
 Ash, grafting a Weeping, 282  
 Asparagus, culture of, 267, 415;  
 seaweed for, planting old,  
 cutting, 438; without beds,  
 487  
 Asparagus beds—and salt, 22;  
 spring dressings for, 96  
 Atherton, presentation to Mr.,  
 409  
 Auriculas—National Society's  
 Schedules, 88, 273; not grow-  
 ing, 123; origin and history  
 of (Hibberd's paper), 396;  
 show, 319; select, 314; im-  
 provement and properties of  
 (Horners' paper), 398; at  
 Kensington, 358; National  
 Society's Northern Show, 399;  
 in Scotland, 373; Alpine, 424  
 Australia, gardening in, 63;  
 fruit, 422, 423  
 Azaleas, treatment after flower-  
 ing, 139, 289; Deutsche Perle,  
 171; mollis Lord Shaftes-  
 bury, 239; crowded, 368
- BACTERIA IN SOIL, 465  
 Bagshot Horticultural Society,  
 422  
 Banana trade, 413  
 Barometers, proposed Exhibi-  
 tion of, 103; historical sketch  
 of, 232  
 Baskets for Orchids, 189  
 Bath and West of England  
 Show, 463, 478  
 Bath Spring Show, 258, 407  
 Beans, sowing Broad, 11; Dwarf,  
 95  
 Beanmontia grandiflora, 339
- Bedding out, 400, 474  
 Bedding plants, propagating,  
 97, 180, 429  
 Bees—prospective management,  
 12; notes on, candy, honey  
 presser, driving, 33; Educa-  
 tion in bee-keeping, 55;  
 abandoning a hive, 56; drones  
 and drone comb, 54; pur-  
 chasing stocks, 77; the  
 weather, 77; enlarging hives,  
 wax, 78; initiatory instruc-  
 tions, 93; abandoning a hive,  
 99; and their enemies, 99;  
 the past honey season—dark  
 side of bee-keeping, 121; super-  
 ing, 120; an amateur's experi-  
 ence, 139; cottager's straw  
 skep, 140; dividing boards,  
 141; about, 167; feeding, man-  
 agement of stocks, 161; tom-  
 tits, 162; Reversible frames,  
 181; balloting for hives, 182;  
 tom-tits, 182; Marketing  
 honey, 199; preventing  
 swarming, difficulties, 200;  
 tom-tits and, 200; extracting  
 honey, 220; honey press, 241;  
 useful hives, 249; shows and  
 judging, 241; useful hints,  
 251; dysentery, roofs, 262;  
 feeding in spring, 262; initi-  
 atory instructions, 281; early  
 swarming, 282; early appear-  
 ance of queen wasps, 292;  
 management of, Rutherglen  
 Horticultural and Apiarian  
 Society, 302; the effects of  
 winter on, 301; in winter, an  
 experiment 322; appliance,  
 frame hives, 323; transferring  
 combs, 324; initiatory in-  
 structions, No. 3, 345; notes  
 on, 366; transferring stocks,  
 366; position of the apiary,  
 367; races of, 367; the season  
 and the, 367; initiatory in-  
 structions, 388; seasonable  
 notes, 389; introducing  
 queens, 411; dysentery, 413;  
 placing and removing supers,  
 430; inciting robbers, 432;  
 hives with frames across, 431;  
 extending a frame hive, 431;  
 queen and drone raising;  
 state of hives; a day's out-  
 ing, 453; placing and remov-  
 ing supers, 474; introducing  
 queens, 475; the way to suc-  
 cess, 497; doings of the week,  
 497; Stirlingshire Bee-keepers'  
 Association, 498; Nutt's hives,  
 robbing, 493; initiatory in-  
 structions, 518; introducing  
 queens, 519; placing swarms  
 into a Stewarton hive, 519  
 Beet, sowing, 213; estimate of  
 varieties, 289  
 Begonias, winter flowering, 46,  
 54; raising Tuberosus, 97, 191;  
 octopetala, 232; Tuberosus,  
 251, 429; propagation of, 445;  
 Messrs. Lalag & Co.'s, 487;  
 Arthur Mallet, 515  
 Belgian horticulturists, meet-  
 ing of, 131; amateur's garden,  
 154; Horticulturists, meeting  
 of the, 251, 503  
 Belvedere House, Wimbledon,  
 136  
 Bertolonias, 180  
 Berberis vulgaris, uses of, 391  
 Birmingham Gardeners' Im-  
 provement Society, 112; Asso-  
 ciation, 198  
 Birds and the weather, 422  
 Black Lily, the, 10  
 Bladder Bloom, the White, 6  
 Blackberries, American, 374, 400  
 Blackbirds, numerous broods  
 of, 503  
 Bog garden, Mr. Paul's paper  
 on, 490  
 Bollers, prizes for, 156; the  
 Rochford, 292; leaking, 303;  
 conditions of (Liverpool) con-  
 test, 395; saddles, 412; new, 419
- Boller, Mr. H., death of, 178  
 Bone manure, making, 141; and  
 bonemeal, 221; dissolving,  
 263; using dissolved, 412  
 Books—Review of "The Kili-  
 ma-Njaro Expedition," 25;  
 "Praise of Gardens," 28;  
 "The Golden Gate and Silver  
 Steps," 43; "Permanent and  
 Temporary Pastures," 102;  
 "Report of Observations on  
 Injurious Insects," 335;  
 "Flowers, Fruits, and Leaves,"  
 470; "How to Grow Peaches,  
 Nectarines, and Apricots in  
 Small Gardens," 487; "Cot-  
 tage Gardening," 487; "Or-  
 chids: their structure, his-  
 tory, and culture," 449  
 Borecole, 187  
 Botanic (Royal) Society's Show,  
 239, 293, 409, 471; Evening Fête,  
 487  
 Bouvardia, lecture on the, 151  
 British Flora, preservation of,  
 273  
 British plants, catalogue of, 399  
 Broad Beans, notes on, 207  
 Broccoli, varieties of, 186; Gil-  
 bert's Victoria, 413  
 Bromeliads, the late Professor  
 Morren's, 442  
 Brown, death of Mr. Wm., 22  
 Brwallia elata, 131  
 Brussels Sprouts, varieties of,  
 186, 197; and early Broccoli,  
 226; Ne Plus Ultra Northaw  
 Prize, 250  
 Bulbs, statistics of the Cape, 39;  
 growers, 345; in the London  
 Parks, 355; at Kew, 355  
 Burghley productions, 291  
 Burn, presentation to Mr., 399
- CABBAGES—AMERICAN FARM,  
 23; for spring, 53; culture,  
 187; scarcity of plants, 273  
 Cadogan Gardens, 360  
 Calanthe veratrifolia, 335  
 Calceolarias—shrubby, 158, 187;  
 blooms, 422; at Bedford Hill  
 and Parkside, 464; culture, 495  
 Calcutta, Royal Botanic Garden  
 at, 89  
 Calendarial notes, 201  
 California, gardening in, 91  
 Callas, 429; a crimson, 44  
 Calotropis procera, 152  
 Camassia esculenta, 422  
 Camellias—not expanding, 170,  
 412; and Rhododendrons, 100;  
 treatment after flowering, 280;  
 pinching young shoots, 412  
 Campanula coronata, 51  
 Canker and insects, 33; in fruit  
 trees, 70, 83, 173, 245, 422  
 Cannas, 98  
 Capsicums, culture, produce, 324  
 Carnations—winter flowering,  
 74; Miss Jolliffe, 82; tree or  
 perpetual flowering, 103, 411;  
 from seed, 388  
 Carpocapsa pomonana, 418  
 Carrots, petiolatum for, 79; in  
 frames, 93; early, 173; prob-  
 able varieties, 285  
 Caterpillars on fruit tree blos-  
 soms, 171  
 Cattleyas—Lawrenceana, 192,  
 230, 235; culture of, 22; Bow-  
 lingiana, 397; Cattleya Men-  
 deli, Duke of Marlborough,  
 423; speciosissima (Patix  
 var.), 470; Mossie Arnold-  
 lana, 515  
 Cauliflowers, 53, 227; and Broc-  
 coliflor succession, 100; trans-  
 planting, 159; varieties of,  
 186  
 Celery—White Plume, 10; cul-  
 ture in Notts and York-shire,  
 17; a "Push-up" for earth-  
 ing, 17; new varieties of, 21;  
 chapter on, 505
- Celosias, 496  
 Centaureas, 98  
 Cephalotus follicularis, 95  
 Cesspool, 368  
 Challenger expedition, botani-  
 cal results of the, 131  
 Chamapeuces, 98  
 Chelsea Botanic Garden, 359  
 Chemical manures, 454  
 Cherry, Tobacco-leaved, 391  
 Chertsey Horticultural Show,  
 512  
 Chicory, 428  
 Chionodoxa Luciliae, 252  
 Chloride of lime, 109  
 Chiswick, supper to the em-  
 ployés at, 171  
 Choisya ternata, 100, 421  
 Chou de Burghley and Chou de  
 Gilbert, 292, 395  
 Chrysanthemums—lecture on  
 the at Hull, 6; exhibiting, 7;  
 and their culture, 9, 68, 83, 126,  
 166, 191, 217, 249, 287, 334, 374,  
 411, 438, 484, 504; in the north,  
 18; cuttings, damping, 21;  
 judging, 21; late varieties, 31,  
 89, 375; selection of varieties  
 for various purposes, 38;  
 notes on, 48; Messrs. Can-  
 nell's new, 47; number of  
 plants to grow, management  
 of young plants, 68; propa-  
 gating, 77; gardeners', 92;  
 training plants for producing  
 large blooms, 166; standards,  
 167; bush and decorative  
 plants, 195; Pompons for  
 large blooms and bushes,  
 naturally grown plants, 217;  
 growing specimens, 231; Py-  
 ramids, 249; Mr. Mawley's  
 list of incurved and Japanese,  
 266; white for market, 282;  
 cutting down, 287; Fair Maid  
 of Guernsey, 293, 422; raiser  
 of Ethel, in Guernsey, 314;  
 single varieties, summer  
 varieties for walls and bor-  
 ders, 334; segetum, 335;  
 arranging groups, 374; early  
 buds, 423; summer treatment,  
 insects, diseases, and reme-  
 dies; fixing sorts, 433; seget-  
 um, Cloth of Gold, 444;  
 placing plants outdoors, 459;  
 first break, crown bud, 484;  
 terminal bud, 504  
 Chrysanthemum Society (Nati-  
 onal), 6; late show, 31;  
 annual meeting of, 69, 108;  
 annual report, 293  
 Cinerarias, 77, 293, 496; curious,  
 218, 232; white, 232; and their  
 culture, 239, 319; at Forest  
 Hill, 377  
 Clapton nurseries, the, 174  
 Clematises, 249; indivisa lobata,  
 232  
 Clerodendron fallax culture, 54  
 Clitanthus punicens native  
 names of, 193  
 Climbing plants, hardy, 289  
 Clubbing remedy for, 132; in  
 Codlin moth and larva, 418  
 Cabbages, 189  
 Cologyne, cristata, culture, 31  
 Colchicum wine, 431  
 Cole, Mr. William, death of, 6  
 Collinsia multicolor, 74  
 Colonial and Indian Exhibition  
 349; Indian vegetable pro-  
 ducts, 384  
 Colonial florists, 349  
 Columbinas, 415  
 Conifers, scale on, 122; history  
 of some, 109  
 Cordylines, rooting the heads of  
 large, 449  
 Corridor, plants for a, 57  
 Country, a day in the, 494  
 Covent Garden Market, fire at,  
 170  
 Crataegus pyracantha not fruit-  
 ing, 79  
 Crocuses, 252  
 Croxteth, 511
- Crotons for decoration, 165;  
 Newmanni, 213  
 Croydon Horticultural Society's  
 fixtures, 251  
 Crystal Palace—Spring Show,  
 258; Show fixtures, 313;  
 Show, 423  
 Cucumbers—forcing, 11, 53, 97,  
 139, 189, 230, 269, 465; nematoid  
 worms in, 193; scorching, 346;  
 culture, 452, 493  
 Cucumber house, boiler and  
 pipes for, 13  
 Current topics, thoughts on, 131,  
 216, 352, 411  
 Custard Apple, 122  
 Cyclamens (and Primulas) at  
 Reading, 137; culture of, 168,  
 283; at the Aigbarth Nursery,  
 212  
 Cyrtopodiums—culture, 169;  
 insigne, 40; ctenanthum super-  
 bium, 62; leucorrhodum, 129;  
 spectabile culture, 222  
 Cyrtopodium Saintlegerianum,  
 197; punctatum var. Saint-  
 legerianum, 254
- DAFFODIL NOTES, 239; MR.  
 Wolley Dod's paper on, 312,  
 340; Sir Watkin, for pots, 314  
 Dahlia, culture, 143; Show in  
 1886, 191  
 Daphne indica, 410  
 Date Palm, 222  
 Davallia feneiculaea, 4, 97  
 Dell, The, Egham, 513  
 Dendrobium Wardianum, 159;  
 noble not flowering, 162;  
 luteolum, 174; Leechianum,  
 crassinode-Wardianum, 239;  
 prunig noble, 336; statiotis,  
 338; fimbriatum oculatum  
 (Paxtoni), 424; in May and  
 June, 454; Wardianum  
 Wrighti, 403  
 Dielytra spectabilis, 449  
 Difficulties and poesy, 79  
 Digging in winter, 86  
 Diplacus glutinosus, 443  
 Dipladenias, culture of, 342  
 Dolg, death of Mr. David, 151  
 Doronicums, 419 draytonensis,  
 515  
 Dracenas, propagating, 53, 336
- EDINBURGH, SPRING EXHIBI-  
 tion at, 294  
 Elders for the seaside, 30  
 Emigrants, a warning to, 273  
 Endive, 423  
 Epacris, culture, 139; after  
 flowering, 280  
 Epidendrum leucochilum, 338  
 Ericas, growing hard and soft-  
 wooded, 139; colorans superba  
 and campanulata, 311  
 Essex Field Club, 65  
 Eucalyptus in a hall, 123; for  
 timber, 119  
 Encharis, destroying mites in,  
 34, 109, 142; mite, 163, 171  
 Euphorbias, culture, 54; jacqui-  
 miflora, 329  
 Eupatoriums, 378, 459  
 Evergreens for lawns, 57  
 Everaert's, M. Jean, Garden, 154  
 Exeter Horticultural Society's  
 Shows, 6; special prizes, 65;  
 the new park at, 171
- FAIRLAWN HOUSE, CHISWICK,  
 73  
 Fairy rings on lawns, 521  
 Farm—prospects in the New  
 Year, 14; the flock 57, 79;  
 Potatoes as food for cows, 102;  
 sheep with swollen lips, 102,  
 144; trial of agricultural

## Farm—continued—

machinery at Kinner, price of manures, 144; permanent pastures, 141, 303; artificial manures, 144; lambing, time, 187; Seed time, 202, 221; seed and manure drill, 202; seed samples, 203; experiments in agricultural chemistry, 204; lame pigs, 204 Webb's sample case of seeds, 224; Dickson's book of the, 223; frozen meat, 223; culture of Mangolds, and manure for, 243, 264; root crops, 243; Kohl Rabi, Swedes, and White Turnips, culture of, 264; Clover and Grass, 283; forage crops, 325; a dairy scholarship, 370; heavy crops and high culture, 392; Indian Wheat supply, 414; seeds at Edinburgh and Liverpool, 434; grass manure 436; condensed milk, 453; entailment in size of farms, 477; sowing Cabbages for cattle, 500; green pastures, 521

Farming, the future of, 347, 369, 392, 413, 433, 453, 499; profitable 101, 123, 143, 163

Farmers—and gardeners, 41, 63, 87, 107, 203, 224; Sutton's "Year Book," 164; small handbooks for farmers, 34

Ferns—history and habits, 8, 20; seedling, 56; potting, 79; notes on, 85; hardy from spores, 100; treatment of Maidenhair, 334; and Orchids, 45; phenomena of variation, in, 479

Fertilisation of plants, 422

Ficus elastica, propagating, 94, 123; repens variegata, 192

Figs—forcing, 76, 139, 180, 279, 387, 56; falling, 141

Fine-leafed perennials, 483

Firing, hints on, 225

Firm oil the best, 450

Fir-tree oil spray pump, 331

Fish potato manure, 168

Fishing, periodical on, 66

Fittonia, 180

Florida, orange culture in, 419

Florists' flowers, seasonable hints on, 119; selections of 163

Flowers—early, 108, 217; economy in the use of, 114; everlasting, 178; Everlasting from seed, 302; for weddings, 274; Show in the Scilly Isles, 274; fresh and fading, 393; shows at school, 422; for market, 432

Flower gardening, 383

Forcing vegetables, 10

Forp, Mr. J. H., presentation to, 170

Forestry—45; report of Committee on, 10, 23

Freesia refracta alba, 131

Frisby, Mr. C., death of, 108

Fritillaria kalmianae, 10; Melegria, 403

Frost—at Chiswick, 22; in March, 192; in 1885, 6, 444

Fruit—exports of, from Tasmania, 80; keeping, 198; fresh from the Antipodes, 336; production in California, 422; stoning, 453, 482; crops in Kent, 508

Fruit trees—planting and pruning young, 35; rabbits eating, 57, 170; canker in, 70, 173; culture of, 106; caterpillars eating blossoms, 151; protecting blossom, 243; protecting, 321; watering borders, 394; pinching and pruning, 413; management of, 432

Fruit garden—the, 82, 76, 159 451, 495; Rivers' miniature, 156

Fruit houses—tar in, 4; and plant houses, arrangement of, 18

Fuchsias for bedding, 56; for decoration, 243

Fungus, edible, 172; destroying, 521

### A NEW YEAR'S GREETING.

**T**HERE are some distinctions which are eagerly coveted. To have a handle to one's name or a string of letters after it; to be a reigning beauty or a distinguished wit; to have plenty of filthy lucre, even in Scotch notes—are all things which create envy towards their possessor. On the other hand, there are distinctions which people may wear without their neighbours in the least degree breaking the tenth commandment because of them. To be the "ugly duck" of the family; to be a poor baronet without a sixpence to call it his own; or to be the "oldest inhabitant," however respected, of the town, are things which most think their possessors are quite welcome to have; and as I feel convinced that the honour of addressing a few words of greeting to the readers of the *Journal* has been given to me for the simple reason that I am one of the oldest, if not the very oldest, contributor to its pages left. It is twenty-five years since I first entrusted my desultory thoughts to its pages. I do not think that I shall be envied the privilege, although some remembering the wise and wholesome words which have been addressed to them in former years by other and abler hands will be inclined to say, "Evidently in his dotage. Why didn't our Doctor get some fresher hand to write to us?" but as the duty has been given to me I must perforce do what I can. When I said to the Doctor, "I will do the best I can." "Of course you will," was his reply; "we expect that." I doubt not the verdict will be, "Bad at the best."

And is not the first word of greeting due to the *Journal* itself? I have been lately looking through in the library of the Horticultural Club some of the very earliest volumes of the *Cottage Gardener* when the *Journal* was in its babyhood. I can't say its long clothes (for the pages were so small) and as I looked at the later volumes I could not but feel how great had been its progress since those days. But not only so. It has had children born to it, and these seem to share the vigour of its parent in the race for distinction. In the competition which it has had to meet with it has more than held its own. Contributors have passed away, honoured signatures are no more to be found to its papers, new ones have taken their place; but I do not think that anyone can say it has deteriorated. It still retains its thoroughly practical character; it is still the journal to which more especially the amateur delights to turn for information, rarely to be disappointed. It still retains that friendly, brotherly character which it has so long held, and should an intruder attempt to disturb this friendly feeling of our family party he is very soon told "You can't lodge here." Bearing all these things in mind surely our first greetings are due to the *Journal* and its accomplished and genial Editor. May both have a prosperous and happy new year, and in a real sense "May this be as the last, and much more abundant."

To the contributors to its pages I would also send my greetings of well-wishing. Many of them occupy the places which have been worthily filled by men earnest in their call-

ing—men who were distinguished among many things for their modesty. True knowledge always makes a man distrustful of himself; a little puffs him up. Some years ago I was talking with a medical man on the treatment of a particular disease. He said something which startled me; but I said, "Doctor, I thought nothing was more certain than in such a disease these things would be injurious." "When I was young," he said, "I thought that I knew everything. After thirty years' experience I began to feel that I knew nothing." The man who in this spirit tells us his thoughts is more likely to be a true instructor, and I rejoice to think there are many such. They feel that they have a very large *clientèle* amongst all classes of the community, and are careful not to advance doubtful matters, or to lead others astray by advocating false theories or unsound practice. To you, my friends, I send my brotherly greeting. Pardon one who contributed to its pages before you entered on this changing scene, if he ventures in giving you all hearty wishes for your welfare and happiness in the new year to say, Remember your responsibilities as teachers of others, and be not will-o'-the-wisps, but true lights.

And what shall I say to the readers of the *Journal*, so varied in their character, so widely scattered in their habitations, so diverse in the gardens which they possess? I cannot perhaps do better than draw a moral from my own past experience. I have for half a century or more loved flowers. I have cultivated them sometimes under much difficulty—sometimes, as now, in more easy circumstances. I have had arduous posts to fill, and have had my share of the troubles and sorrows that are our assured portion here; but I can fearlessly say that among the things which have helped me and enabled to take a right view of things few have been of greater service to me than my love of flowers. Many of my most cherished friendships have originated through it; many of my pleasantest hours have been spent with those who have had a common interest with me in that love; in days when the head has been overtaxed, to throw work on one side, and to go into one's garden, dismissing for a while more serious matters, or in days of trouble to find the flowers speaking to us of that love and goodness which has made our earth so full of beauty, bearing withal its marks of decay to remind us of those realms into which decay never enters. All these make me say to the readers of the *Journal*, Cherish your love of a garden. Oh! how many are the advantages we possess now to what we did fifty years ago! Then greenhouses were only the luxury of the wealthy, whereas now they are almost the necessity of every lover of a garden. See how the world has been ransacked during the last half century to provide for our gardens, and think yourselves fortunate that so many are catering for your benefit, and placing such treasures within your reach. Let me give one word of caution—Do not attempt things which either your circumstances or your locality will not permit you to do thoroughly. When I see anyone in a smoky locality attempting to grow Roses, or another attempting to grow Rhododendrons on chalk, I pity the misdirected energy which must result in failure. Attempt what is possible, not what is impracticable, and don't get beyond your depth. It is possible even with flowers to do this, and it can only be a worry instead of a pleasure. Why turn your honey into gall? Why make what is intended for your happiness be an occasion of falling?

A good deal has been said of late about honours to horticulture. Some have written with a high sense of virtuous repudiation who would be amongst the first to welcome them if proffered to them; and others have thought it would be well that they should be given to them as well as to other callings. I think we may leave such matters to settle themselves. It is a happy thing in our dear land that while titles are not treated with the assumed contempt they are in some countries, a man is never less esteemed of because he lacks them.

And now as we look forward into that coming year of

whose tangled skein we know nothing, and of whose bearing on our favourite calling we are equally ignorant. Whether we have bright skies or cloudy days, enter upon it with a good heart. I speak not now of higher and holier things, for I am not here to sermonise. Faint heart never won fair lady; and our fair Flora, though no way coy, likes her lovers to be bold and courageous. Make use of all the many advantages you possess. Let "Forward" be your motto; and to one and all let an "old boy" wish you a very happy and prosperous new year.—D., Deal.

### KEEPING APPLES.

BEFORE plunging into this question we may preface what has to be said thereupon with a few remarks on gathering the fruit. At the Edinburgh Congress in November the fact that large quantities of the fruit had been removed from the trees long before it had arrived at the stage when it was ready for gathering was most patent. Some collections were in almost every dish showing the unmistakeable symptoms of premature removal, and how the bulk from which these samples had been selected were to weather the succeeding four or five months during which Apples would be wanted was to us a question that admitted of no solution. From that it would appear that many of the Apples in the north are gathered before they are ready, and it would follow that many gardeners have not considered the matter as they ought. We have unfortunately been obliged to remove a large quantity of fruit from the trees before it was quite ready, and that on account of the multitude of "songsters" which have to be fed at the period the earlier of the main crop sorts are swelling off, but the later kinds have been quite safe from the birds. There are some simple rules which have been laid down in order to help the inexperienced to judge as to the fitness of the fruit for removal, such for instance as the pips ripening and the ease with which the fruit parts from the tree on testing it; but neither of these tests is infallible, and nothing is to be found to take the place of a tried judgment. If trees are heavily cropped, or if the soil is very dry, fruit will be easy to detach from the tree even before it is ready.

The Apple, like other fruits, has its "swelling" stages, and it is very often during the period of its last swelling that much fruit is gathered. A good plan, in fact the only sensible plan in gardens, is to gather the largest of the fruit as it becomes fit, leaving the smaller and greener for a longer period until it also is fit to gather. We have often our best fruit, either as regards size or colour, from the fruit thus left. We have so large a quantity to gather that the rules laid down by some pomologists as to the handling of the fruit, such as laying it in single layers in wadded trays and careful removal on to shelves in the fruit room, are matters which we cannot compass; nor is it at all necessary unless in the case of fruit selected for any special purpose. Large baskets with side handles are admirably fitted for carrying the fruit, and with ordinary care it receives no damage; all fruit that is ready parts quite easily from the tree. It should be taken in the hand and bent backwards without twisting. If fruit requires to be twisted off it is better left on the tree until it will come off without it.

Gardeners have to put up with such means as they have provided them to keep fruit. Some of these rough-and-ready buildings which we have seen are much better adapted for preserving fruit in good condition for a lengthened period than the most pretentious and expensively fitted structures we have had the privilege of inspecting. The interior arrangement of an Apple room need be of only the simplest nature, room to walk and to work among the fruit and shelving to carry it is all that is required. The pathways should be wide enough to allow all the work required to be easily performed, and the shelves should be as wide as they can be conveniently managed, constructed of close boards, and with deep sides to keep the fruit in. In order to promote ease of access the tiers of shelving should not be too close together, and this is of the less consequence, as we have proved that Apples keep quite as well banked up in heaps as they do laid out singly. The only precautions necessary are to put in no damaged fruit, to gather and store in dry weather, and to wait until the fruit is ready before gathering it. During the time the storing of the fruit is progressing a current of air should be allowed to pass through the structure, and this should continue for a week or two after the shelves have been filled. The important feature to study after the fruit has been stored is to keep the room at an equal temperature, if possible not below 40° and not above 45°. A thatched and air-encased lean-to with a high wall on its south side, an outer and an inner door with a short entry between, and one solitary window which could be blocked up with straw and shuttered from the outside would please as perfectly for a fruit room; as it is we have to go on with a very roughly fitted building, and in those points

wherein it comes short of what we should wish it to be we endeavour to meet with such appliances as we can readily call into use.

It is very generally supposed that Apples will not keep well unless the storeroom in which they are placed is secluded from light; but we have repeatedly kept Apples in good condition as long as it was possible to keep them in a lighted apartment. The real benefit derived from the exclusion of light would appear to be that the air inside the building is kept at a more regular temperature by means of shutters acting to some extent as non-conductors of either cold or heat. In changeable weather, such as recurring frosts with their accompanying thaws, we have stuffed the outside of the windows well up with straw, and in this way kept the fruit from such sudden and excessive changes of temperature as they would otherwise have had to experience. In long-continued severe frosts we cover all the fruit with layers of newspapers, which are in themselves a great help. We also keep a few petroleum lamps going, and on occasion made charcoal red hot and shut it up in an old saucepan. The thing to keep in mind when applying artificial means of keeping up the temperature is to endeavour to keep the temperature from lowering beyond a given point, for this is much easier of accomplishment than to raise the temperature after it has fallen, while the fruit, as a matter of course, is better kept under the former conditions than under the latter. It is a safe plan to keep the fruit shut up and covered for a while after open weather is established. It may be necessary to allow a current of air through the building in order to dry any accumulation of damp which may have settled on the fruit; care, of course, must be taken to choose a hard drying breezy day for this purpose.

As to the removal of decaying fruit, we have not found that to be an undertaking of any great moment when the following rules have been followed—viz., to store only good and unblemished fruit; to have all fruit removed as it becomes ready for use, and in cases where sorts keep a good while after they are ready for use to see that these are all used before decay begins; and generally to carry out the matters of detail mentioned in foregoing remarks.—B.

### THOUGHTS ON THE PAST YEAR.

WERE I to venture to say all I think on the events pertaining to gardening and the cultivation of the land generally during the past year, it is almost certain I should "tread on somebody's toes," and that would be quite out of harmony with the sentiments of the season when everyone is wishing each other a happy new year. In this wish I share sincerely, not towards those who have agreed with me alone, but equally to those who have differed; and especially with these latter, no matter who they are, nor how strong they have been in their opposition, I would like to "tak a cup o' kindness for Auld Lang Syne."

I AM not at all certain that the year that has just closed has been one of the brightest and best for gardeners generally, and it is certain it has not been prosperous for their agricultural brethren; but I think this—that there has been more despondency on the part of farmers than is justified, and that they have not striven with the same zeal to meet and overcome obstacles as gardeners have. There seems to have been a resting from strong effort on the part of agriculturists in the lurking hope that some magician's wand would by a miraculous swoop suddenly bring prosperity to an "oppressed" community. I believe in no such things. Farmers have "given up," gardeners have "plodded on," and the result is that gardens have been as productive as ever all through the depression period, but farms have not. The only safe and sound principle to act upon in good and bad times is to make the best of opportunities; and the greater the difficulties the greater should be the efforts to surmount them.

It has become almost a habit to think and say that "times" were never so bad as now. If my memory is not deceptive I have known them decidedly worse—worse for everybody, labourers, farmers, gardeners, landlords. I can remember when wages on farms and in gardens were at the least 10 per cent. lower than now and the necessities of life, on the average, 10 per cent. higher—that is, 20 per cent. in favour of the present over the "good old times" of the past; while the national rent roll now is certainly greater than it was then, notwithstanding the "reductions." I can well remember the time when garden and farm labourers received 10s. a week on an estate where the wage rate is now 20 per cent. higher, and the rental of the same estate is much greater now than it was then. Farm produce was lower in price than it is now—mutton 4d. to 6d. a pound at the butcher's; butter 8d. a pound; eggs twenty-four for a shilling; oats 15s. a quarter; barley 25s., and Wheat as low as it is now, sometimes, at others a good deal higher. But farmers "lived" and paid their rents then. Why cannot they do so now?

THE truth about the whole matter in my opinion, as regards the relative prosperity or otherwise of the "times," is not to be found in the rent roll of one man or the wage of another, but in something else. It is not the earning, but the spending in which lies the sequel of the present "depression." A term of inflated prosperity begot a more luxurious style of living. The faster money was made the more lavishly it was spent. Agriculturists innumerable were drawn into the vortex and had no balance at the bankers when the time of trial came. They had to limit expenditure by restricting labour, stock, and fertilisers, and as a

natural consequence the land became infested, and in the case of thousands of acres practically "eaten up" with weeds. That is the certain road to ruin, and is the root of the evil of falling rents that is so much to be deplored.

PERMIT me now to express my thoughts very plainly on a public question of vital import. If I were a landlord and had tenants who had been accustomed to pay, say £2 an acre for the land in the so-called "good times," but now by gradual reductions pay little, if any, more than half the amount, and still not satisfied, I should make no further abatement. I am beginning to think that rent reduction is a sort of fashionable epidemic, and that the more it spreads the worse is the farming. If a man with a thousand acres of land that, if well managed, would grow five or six quarters of Wheat per acre, cannot pay 25s. an acre and live, I believe five men with two hundred acres each can. The better the rents, in reason, the better is the farming as a rule, and it is a question if "reduction" is not in danger of being overdone. One great landlord has stopped it effectually by reminding his tenants that he had received no requests from holders of medium-sized farms for any further abatement. They will all farm better now.

BUT what has this to do with horticulture? It has a very great deal to do with it. If the rents of the large estates of this country are allowed to glide away to nothing, how is horticulture to be supported and high-class gardening to be maintained? For my part I like to see a flourishing aristocracy, the land worked well and capable of yielding more food and leaving a good margin for rent. That is surely not antagonistic to a rich mercantile community. Is it not rather the reverse? And does it not follow that the greater the proceeds from land or commerce the better are the emoluments of the wage-earning class? Amidst all the "depression" I am more "depressed" by the falling wage rate than anything else. If the millions cannot earn money to spend, general stagnation must sooner or later prevail.

I AM of opinion that bringing down wages to the lowest possible point is of benefit to no one, but acts prejudicially all round. What does it mean? It means less work—limited production. Taking the community throughout, if wages are reduced 5 per cent. the value of labour given in return will fall in greater proportion. Nothing can prevent this. However high the profession of individuals, or humble their calling, they give their services grudgingly or willingly according to emoluments. It is always better to face facts than to shirk them. If low wages were conducive to prosperity low wage counties would be the richer and high wage districts the poorer. Exactly the reverse is the case. And it is precisely the same with nations. So-called "cheap" labour, like "cheap" shoddy-made goods, which ought to be ticketed "bads," are dear in the end. The principle applies to gardeners, for I must not forget them. Thoroughly competent men, well paid, give in return their honest hearty services, never knowing when they have done enough; but the underpaid crawl their time over grumblingly, and these are the really unprofitable. Perhaps I shall not be able to make wage-payers believe this, but however that may be, I am convinced of the absolute truth of the statement, which is not made in the interests of a class but for the mutual benefit of all concerned.

I SHOULD now like to say what I think on another matter, which the experience of the year suggests as worthy of attention. It is an old habit that seems to need checking—the over-manufacture of gardeners. Now that so many labourers need employment it would be better that more of these be accustomed to do much of the work that is done by young men who, by-and-by, will find it difficult if not impossible to obtain appointments such as they desire, and who will either have to quit the country or take refuge in the army or police force. Why should men be trained for positions they can scarcely hope to fill, while at the same time labourers with families are only one remove from the workhouse? The rates are heavy enough now. A change in the direction indicated would be of benefit to all—to the young men who would be directed to some other field of labour, to village workmen longing for employment, to owners of gardens, and to ratepayers.

ONE way of limiting the manufacture of gardeners would be to abolish the premiums that students have to pay, compensation being made to those gardeners who have benefited by the "vested interests"—that is to say, where these have been enjoyed in lieu of additional wages. It is in that light they are regarded; but it is tolerably certain that the noble and the rich never think that young men or their parents are impoverished to defray the expenses of the establishments of the wealthy. I wish some nobleman would set the example of settling this matter equitably, and the few pounds of compensation he would pay would be saved twice over. When a gardener takes a premium with students he is almost obliged to keep them for a considerable time, however unprofitable they may be; he is bound by a custom that is economically unsound and ought to belong to the things of the past.

I WOULD next venture to bring under review for a moment another practice that is increasing and developing. A few years ago, when produce was sold from the gardens of the nobility and gentry, it was not done openly as a trade, but in a quiet unobtrusive manner. Things are different now. No secret is made of the practice, and numbers of gentlemen's gardens are in reality "market gardens," fruit, vegetables, flowers, and even trees being grown for sale, the gardener having a commission on

the proceeds to stimulate him in making money. Any nobleman or gentleman has a perfect right to do that. He can even feel the work is a benevolent one, inasmuch as he enables the inhabitants of the adjacent town to obtain better "garden stuff" at a cheaper rate than before. It is certainly better to sell what others want than to waste it. That must be conceded; but there is another aspect of the question. Since, say, £500 a year have been made out of a private garden, its assessment for rating purposes has not been increased one farthing; but if Brown by his frugality saves a little money and commences as a market gardener just outside the park gates, his assessment is increased with every greenhouse he builds, until eventually he is taxed 100 per cent. higher than his great rival, and mayhap a good deal more. Brown, who is struggling for a livelihood, is as, I think, unfairly handicapped by the greater burden he has to bear because of the exemption of his neighbour and powerful opponent in business. We hear a good deal about "fair trade" nowadays, but I do not call it fair for one of two persons, who are engaged in the same calling, to enjoy such an extraordinary exemption from local rates, and the other—he whose livelihood depends on his labour—to be correspondingly overburdened. As this is neither a personal nor a political question, it is eminently proper for discussion on its merits. But what is the use of opening it, it may be asked, without suggesting a remedy? Well, here is a proposal.

THE owner or occupant of every private garden who competes with regular traders in supplying the markets openly or in a semi-private manner with fruit, flowers, or vegetables should in my opinion be assessed, or at least his garden should, at precisely the same rate that regular trade establishments are in the same district. Against this it may be said the produce sold from one private garden may amount to £500, while that from another may not amount to a tenth of that sum. No matter. If a person does not like the extra assessment he has the remedy in his own hands—he can give up marketing; or, on the other hand, if he be willing to endure it and make the best of it, he can extend his operations. This private trading in Grapes, Orchids, and other things under exceptional circumstances is of no benefit except to those who engage in it, while it places a large class of regular traders in a most unenviable position, inasmuch as it, in effect, reduces their business and raises their rents. I know very well that gentlemen pay a tax that market gardeners do not—a tax on their gardeners as domestic servants. It would be better to abolish it in the case of those who trade, and thus place all on the same footing by an absolute equality of assessment than to leave open a grievance, that one class of the community is favoured at the expense of another. But I must pause.

I HAVE been obliged to observe what seems an absurdity during the past year—Apple trees groaning with fruit that could scarcely be sold at any price, while a month or two afterwards (and now) markets were supplied with American produce. Here is the humiliating spectacle of Apples being sent 3000 or 4000 miles to market while home-grown fruit is going a-begging. How is this? Simply that transatlantic growers have planted freely and exclusively the most tempting market varieties, while in this country there has been no systematic action in improving the supply of useful fruit; or at least it did not commence soon enough, and Britishers are, for the time, left behind their rivals in the competition.

MY thoughts have not run in a particularly cheerful groove so far, but things will come right in time, as they have come right before after worse periods than this. John Bull when rolling in rich pastures is apt to become lethargic, but he moves with persistent force when he is hungry. He is not in a moribund state, though temporarily depressed. He will brighten up by-and-by, rents will be firmer with better culture, and this will follow because it is a necessity of existence, trade will revive, and wages increase, and a more prosperous future is in store for those who shall labour and will be permitted to wait; at least such are the convictions of—A THINKER.

P.S.—"Current Topics" have had to stand aside for a consideration of greater and more general subjects, and in respect of recent episodes I can only thank Mr. Harrison Weir for the information that he objects to being referred to as an "individual." No one could, of course, have anticipated such an objection, and I certainly shall not employ the term again, or at least apart from the well-merited adjective "distinguished." The fact is, I have for years been a great admirer of Mr. Weir's talents, and have regarded him as one of the distinguished men of our generation.—A. T.

## PLANTS CERTIFICATED IN 1885.

MR. B. S. WILLIAMS.

FOR many years the Victoria Nurseries, Upper Holloway, have annually contributed largely to the novelties submitted to public attention, and so much care has been exercised in the selection that a good proportion have obtained prominent positions amongst the best of garden plants. Nurserymen contribute greatly to their reputation by judiciously excluding all novelties of doubtful merit from their lists; purchasers are saved much annoyance, and, indeed, are encouraged when they find they can rely upon obtaining something both new and useful. It is an important matter to secure the confidence of the public, in trade it is in fact the secret of success.

From the plants Mr. B. S. Williams has had certificated during the past year a dozen excellent novelties may be selected as worthy of special notice, and, taking them in alphabetical order, the first to demand atten-

tion is *Amaryllis Comte de Germiny*. This is one of the winter-flowering group obtained from crosses with *A. reticulata*. One handsome form of this type, Mrs. Garfield, has already secured much favour, which the *Comte de Germiny* is likely to share. It has flowers of good size, veined and streaked with rich crimson, and having a clearly defined white bar in the centre of each petal. They are borne on good heads on stout scapes, the leaves being much broader than *A. reticulata*, but with a white midrib. Plants are now flowering in the Holloway Nursery, and continue attractive for some months during the duldest season. All the plants of the type are thoroughly useful, easily grown, and flower freely.

Amongst the *Calanthes* a section is being formed of species or varieties that flower much later than the ordinary *C. vestita* or *Veitchii*, thus considerably prolonging the season during which their pleasing blooms can be supplied. One of the latest introductions in this group is *C. Sanderiana*, for which Mr. Williams has been awarded first-class certificates both at Regent's Park and South Kensington. It may be termed a highly coloured late *C. vestita*, but is much superior to most forms of that Orchid,

comes next in order, *Dendrobium nobile* var. *nobilius*, and although so much has been written in its favour it amply merits all the praise. The colour is exceedingly rich, far surpassing all other forms of this useful Orchid, and the flowers also are unusually fine in size and of good form. A trio of other good Orchids may be added to this—namely, *Lælia purpurata* Williamsi, *Masdevallia Harryana lateritia*, and *Odontoglossum hystrix magnificum*. The *Lælia* is a superb variety with flowers of great size, the sepals and petals crimson purple, the lip intensely rich dark crimson; it is one of the most magnificent *Lælias* in cultivation. The *Masdevallia* is remarkable for its glaring crimson colour, and the *Odontoglossum* for its beautifully formed flowers, brown tipped and marked with yellow.

*Hymenocallis macrostephana* is gradually becoming recognised in gardens as a useful stove flowering bulb, and its increasing popularity is no doubt due in a great measure to the specimens shown by Mr. Woodbridge, gardener at Sion House, who grows and flowers it admirably. The flowers are pure white, in the way of the *Pancratiums*, and are borne on stout scapes in umbels of good size. *Nepenthes Excelsior* is a hybrid

Fig. 1.—*DAVALLIA FœNICULACEA*.

the flowers being very bright crimson with broad lips. Two other notable Orchids are *Chysis lævis superba*, a grand variety with rich brown and yellow flowers in strong spikes, and *Cymbidium elegans*, which has long tubular yellowish buff flowers in dense pendulous racemes. The foliage is somewhat like *C. Lowianum*, and it resembles that in strength of habit.

Though not one of the certificated plants of 1885, a Fern which has previously received dual honours may be mentioned, more especially as its merits do not seem to be fully recognised at present by those who give particular attention to Ferns, but who can only have those that are free in growth and graceful in habit. This is *Davallia fœniculacea*, the Fennel-like *Davallia*, a most elegant, easily grown Fern, alike pleasing in a small or a large state. It is a native of the Fiji Islands, and produces fronds which at their full size are about 2 feet long and 1 foot broad, very finely divided and gracefully arching or Plum-like. As may be judged from its native home, it requires a stove temperature, but it is readily obtained in good condition, young plants being exceedingly useful for decorative purposes, reminding us of some of the more elegant *Aspleniums*. The woodcut with which Mr. Williams has favoured us truthfully represents a specimen of medium size.

Returning again to the plants of the present year, a famed Orchid

between *N. Hookeriana* and *N. Rafflesiana*, and bears abundant medium-size pitchers mottled with bright red, a useful Pitcher Plant to be recommended both for its habit and colour. *Pavetta montana* is a stove plant of shrubby habit, bearing clusters of white flowers in the axils of the leaves, and will be useful, as it flowers in a small state. To conclude our selection we may mention *Sarracenia Buchani*, a hybrid between *S. rubra* and *S. purpurea*, producing pitchers 8 inches high, with broad rounded lids of a dark red colour.

Nurseries are seldom very gay in January, but Mr. Williams has a number of attractions in his Orchid houses, and many more advancing, so that in the course of a week or two, with fine weather, there will be abundance of flowers. The general stock of fine-foliage and other plants is in as healthy flourishing condition as could be wished, while the increasing activity in all departments indicates the approach of the busy season.

#### TAR IN FRUIT HOUSES.

MANY years ago I had much difficulty in keeping early Peaches from being entirely destroyed by woodlice. Among numerous remedies I adopted tar, but, like others, did not eradicate the woodlice, and it was most

injurious to the Peaches which were ripening. I smeared the tar on paper and tacked it to any vacant spaces on the back wall, keeping the fruit and foliage clear. The flavour of the Peaches became so strongly impregnated by the tar that they were rendered worthless, and gave much disappointment, the family living at their London residence, and Peaches during June and July are much valued.

Referring to Rood Ashton, I have a distinct recollection, when living there as foreman, that the depredations of the wasps at the gardens was such as I never saw elsewhere, and not confined to one season, but each of the four seasons while I was there we had our patience most severely tried with the wasp pest. I fear that if I were to give the numbers of wasp nests which were destroyed in an area not very wide around the gardens my statements would be discredited. Morello Cherries (which I have seen finer at Rood Ashton than elsewhere), Red Currants, and other late fruits on walls, could not be saved but by carefully fastened hexagon netting.—M. TEMPLE.

## POTATO CULTURE AND EXPERIMENTS.

THE following summary of results of experiments made at Chiswick in 1884 and 1885, for the purpose of testing the efficacy of the system of "earthing-up" advocated by Mr. Jensen, was read by Dr. Masters, on behalf of the sub-committee appointed to carry out the experiments, at the last meeting of the Scientific Committee of the Royal Horticultural Society.

This official document, which was read on December 8th, did not reach us till after our pages were prepared for press on December 30th, which explains the delay in its publication.

THE experiments made at Chiswick for the purpose of testing the value of the Jensenian plan of moulding Potatoes as a preventive of the Potato disease were carried out in the present year in essentially the same manner as in the preceding year. A few slight modifications were adopted to facilitate the making of the record, and the tubers were placed at rather wider distances, the rows being now 4 feet apart, but these changes did not in any way interfere with the fair comparison of the results of the two years, the number of plants in each row being the same. The chief difference in 1885 consisted in the longer time the Potatoes were left in the ground. Thus in 1885 the longest duration of moulding was 118 days on section I. of each row, as contrasted with eighty-three days in 1884. The shortest moulding period in 1885 on section V. was sixty-two days, as compared with twenty-seven days in 1884. The Potatoes were examined on March 31st by the Committee, previous to planting, and all diseased and "suspicious" tubers eliminated. During growth they were inspected at stated intervals, and their condition noted. The season was for the most part warm and unusually dry, and no appearance of disease was noticed at any time on the haulms. On the 10th of October, the weather for some days previously having been wet, the tubers were lifted and carefully examined by Mr. Shirley Hibberd, Dr. Masters, and Mr. Barron. Two unmistakeably diseased tubers were noted during the uplifting on row 3 (Adirondack); and three on row 2 (Recorder). Others that appeared suspicious were sent to Mr. George Murray, who, after adopting appropriate methods of cultivating the fungus, reports that only one was really diseased. It should be remarked that the peculiar red spots in the substance of some of the tubers noted the previous year were not observed at all, though carefully looked for.

As the immediate object of the experiments has again failed in its fulfilment, owing to the slight development of the fungus, a detailed report seems unnecessary, though the documents are at hand for preparing it if thought desirable. A few general remarks, based on the results of the two years taken together, may be of interest.

1, The amount of produce under the varied conditions of the experiment.

2, The effects of long or short periods of earthing-up, and of not earthing-up at all.

3, The consequences of bending the haulms in the manner recommended by Mr. Jensen.

4, The results obtained from planting whole tubers and cut sets.

1, *The aggregate produce* from all the rows of Recorder in 1884 was 257 lbs.; in 1885, 254 lbs. 8 ozs., showing a decrease of 2 lbs. 8 ozs. in 1885, and a total amount for the two years of 512 lbs. 8 ozs. The corresponding figures in the case of Adirondack are 455 lbs. 9 ozs. in 1884, 434 lbs. 12 ozs. in 1885, showing a decrease of 20 lbs. 13 ozs. in 1885, and a total amount for the two years of 890 lbs. 5 ozs. Thus the actual produce of all the rows of each variety was so nearly alike in the two years as to be all but practically identical. On the whole there was a decrease in 1885, in spite of the tubers having been allowed to remain longer in the ground than in 1884. This decrease may perhaps be accounted for by the prolonged drought, but the close approximation in the amounts of produce in the two years respectively seem to afford an indication of the success of the method employed in carrying out the experiments.

2, *Effect of Earthing-up on the Amount of Produce.*—When the results of the two years are combined it comes out clearly (in the case of Recorder), under all conditions of growth, that the greatest weight of produce (irrespective of quality) was obtained from those sections (IV. and V.) which were earthed-up for the shortest time. Some of the largest tubers were met with in these sections, but mixed with a large number of smaller tubers, while their general quality was even and relatively bad.

The same general remarks do not, however, apply to Adirondack, which shows more variation in this respect, and in which the largest, as well as the best and most even tubers, were frequently found in those

sections which had been earthed-up for the longest time. It may be suggested that the results obtained show the probability that the process of earthing-up differs in its effects materially in the case of different varieties of different habit of growth, texture, &c. At any rate, it may be useful to call attention to this subject with a view to future experiments, the more so, as little or nothing is known of the relative effect of earthing-up on different varieties.

*Potatoes Grown Without Earthing-up.*—In both years four "control rows" were planted, two of each variety, the object being to afford a comparison between the Jensenian system of moulding and the natural condition of growth in which no "moulding" at all occurs.\*

The total produce for the two years on row 5 (Recorder, whole) amounted to 100 lbs. 4 ozs., an amount considerably in excess of the yield from any of the moulded rows of this variety (row 2, 84 lbs. 6 ozs.; row 8, 91 lbs. 13 ozs.). On row 11, where cut tubers were planted, the yield for the corresponding period was 87 lbs.—also somewhat in excess of the crops on the corresponding two rows subjected to moulding (row 1, 68 lbs. 1 oz., and row 7, 80 lbs.). The tubers on row 5 and row 11 were noted as much mixed in size; some of those on row 5 being much coarser and larger than on the other rows of the same variety, while many others found lying on the surface were green and small. They had also been the subject of insect attack and injury by slugs and millipedes to a much greater extent than the tubers in the other rows.

Of Adirondack left to itself the total produce of the whole tubers (row 6) for the two years was 186 lbs.—an amount greatly above the quantity on the corresponding moulded rows (row 4, 129 lbs.; row 10, 150 lbs. 14 ozs.). In the case of the cut sets (row 12) the total amount (for the two years) was about the same—viz., 182 lbs. 14 ozs., and also largely in excess of the corresponding moulded rows (row 3, 113 lbs., 5 ozs.; and row 9, 128 lbs. 6 ozs.). The same remarks as to quality apply to the unmoulded rows of Adirondack as to those of Recorder.

It is clear, then, that under all circumstances the actual produce was greater in the unmoulded rows, but that, while some excellent tubers may be grown in this way, the general bulk is much mixed, comprising numerous tubers unfit for consumption, but what might possibly have some advantage (so far as the plant is concerned) in point of physical health over those moulded-up. The small green tubers, for instance (if not affected by disease), might furnish stronger plants than those grown beneath the surface, while their noxious flavour might repel rather than attract predatory insects, &c.

3, *The Effect of Bending the Haulms or Otherwise.*—In each year two rows of each variety were allowed to grow without interference, while in other two rows of each variety the haulms were at regular intervals of time bent downwards. There was no opportunity afforded in either year of testing the value of this practice as a preventive of disease, but the average amount of produce for the two years from the erect and the bent tops respectively shows the effect of the check to growth occasioned by the bending. The average produce of the two years on rows 7 and 8 (Recorder, erect tops) was 81 lbs. 6 ozs., on rows 1 and 2 (bent tops) 76 lbs. 2 ozs.

The corresponding figures in the case of Adirondack are 139 lbs. 10 ozs. for the unbent haulms (rows 9 and 10), and 126 lbs. 1 oz. for the produce of the bent tops (rows 3 and 4).

4, *The Effect of the Employment of Whole Tubers or of Cut Sets.*—In the control rows, as before stated, the greatest weight of produce of Recorder in both years was obtained from the whole tubers, the totals being 100 lbs. 4 ozs. on row 5 (whole), and 87 lbs. on row 11 (cut).

In the case of Adirondack, the total produce in the case of the whole tubers (row 6), = 186 lbs., shows only a slight excess over the yield from the cut tubers (row 12), = 182 lbs. 14 ozs. In 1884 the produce from the cut tubers (95 lbs. 10 ozs.) was slightly in excess of that from the whole tubers (91 lbs. 4 ozs.); in 1885, however, the balance is much in favour of the whole tubers—i.e., 94 lbs. 12 ozs., as against 87 lbs. 4 ozs.

The whole tubers of Recorder subjected to moulding in various degrees, yielded in the two years a total crop of 176 lbs. 3 ozs.—i.e., 91 lbs. 13 ozs. from erect, and 84 lbs. 6 ozs. from bent tops.

The cut tubers of the same variety for the same period supplied 141 lbs. 1 oz., = 80 lbs. from the erect, and 68 lbs. 1 oz. from the bent tops.

The whole tubers of Adirondack produced a yield of 279 lbs. in the two years, of which 150 lbs. 14 ozs. were yielded by the erect, and 129 lbs. by the bent haulms.

The cut tubers of the same variety yielded during two years a total of 241 lbs. 9 ozs.—viz., 128 lbs. 6 ozs. from erect, and 113 lbs. 3 ozs. from bent haulms.

In general terms it may be stated, as a result of these experiments, that (1), earthing-up produces a crop of more uniform and of superior quality, though less in actual quantity. (2), That bending the haulms occasions a diminished yield. (3), That a larger aggregate produce is derived from planting whole tubers than from the employment of cut sets.

[Elaborate tables are formulated, but as these merely give the weights of the produce of the different rows in pounds and ounces, proving nothing more on the main question than is given in the above excellent summary, we do not think the space of this Journal would be usefully occupied by their publication.]

\* It may here be noted that no special rows of Recorder or Adirondack were set apart and moulded in the ordinary way, because, for the immediate object of these experiments such a course was unnecessary, the experimental rows being contiguous to a large area devoted to the cultivation of numerous kinds of Potatoes in the usual way, so that had the disease appeared ample means of testing the effects of the ordinary, as compared to the Jensenian system, would have been afforded.

THE publication of the index for binding with the numbers of the last half-year compels us to hold over several interesting articles till next week.

— A WELL-KNOWN plant-grower, MR. WILLIAM COLE, died at Didsbury, Manchester, on the 26th ult. He was a skilful cultivator of hardwooded plants, and was for many years a successful exhibitor at Manchester and other leading shows. He had been latterly employed by Mr. W. Broome at Fairlawn, Didsbury.

— WE also learn that MR. WILLIAM KEMP, who had been thirty years gardener to the Duke of Northumberland at Albury Park, Guildford, died on the 23rd ult., at the age of fifty-five.

— THE DEVON AND EXETER HORTICULTURAL SOCIETY will hold their shows this year on the undermentioned dates:—Friday, 20th August; Friday, 12th November. The Trustees of the Veitch Memorial Prize Fund have allotted a Veitch Memorial medal and a prize of £5 for competition at Exeter in 1886, the competition to be confined to the county of Devon. The Committee of the Devon and Exeter Horticultural Society have resolved that the medal and prize shall be given for a collection of vegetables, to be competed for at their summer show (20th August).

— THE following are the dates of the meetings of the ROYAL HORTICULTURAL SOCIETY'S SCIENTIFIC, FRUIT AND FLORAL COMMITTEES, IN 1886.—Scientific Committee—January 12th, February 9th, March 9th and 23rd, April 13th and 27th, May 11th and 25th, June 8th and 22nd, July 13th and 27th, November 9th, December 7th. Fruit and Floral Committees—January 12th, February 9th, March 9th and 23rd, April 13th and 27th, May 11th and 25th, June 8th and 22nd, July 13th and 27th, August 10th and 24th, September 7th and 21st, October 12th and 26th, November 9th, December 7th.

— WE are informed that the STOKE NEWINGTON CHRYSANTHEMUM SOCIETY held a special general meeting on Friday evening last, at the Highbury Athenæum, Highbury New Park, the chair being taken by Mr. J. Hicks (one of the vice-presidents). The proceedings opened by the chairman reading the circular calling the meeting, which was in effect to consider the advisability of holding the next exhibition at the Highbury Athenæum. Letters were read from several gentlemen, who were all of opinion that if the next exhibition is held at this place it would be very beneficial to the Society. The matter was then freely discussed, and the following resolutions were agreed to—viz., 1st, That the Society should in future be called The Stoke Newington and Highbury Chrysanthemum Society, and that the next exhibition should be held at the Highbury Athenæum. 2nd, That the days on which the Exhibition should take place shall be the 4th and 5th November next. Another general meeting will shortly take place, when the rules and schedule will be entirely revised.

— IN reply to "J. R.," page 539, who asks for information on FILLING ICE HOUSES, "G. C., Caterham Valley," sends the following:—When in the gardens of Dysart House, Fife, in 1869, and at Broxmouth Park near Dunbar, I assisted in filling two ice houses, and the way we proceeded was to bring the carts to the bouse, and break the ice in pieces about 3 or 4 inches square, and then fill the house, three of us being inside with hammers breaking the ice as small as we could, in fact trying to fill every crevice, and when I went to see it in the summer it was in one solid mass. We filled the house and then filled the inside of the door with straw. Both these ice houses were built in the shape of an egg, sunk in the ground, and in places where the sun's rays had no effect on them.

— THE Executive Committee of the HULL AND EAST RIDING CHRYSANTHEMUM SOCIETY having in view the special object of the Society—viz., "To promote and improve the cultivation of the Chrysanthemum in the district," have considered it desirable to engage an expert to give a lecture on this subject. The Committee have therefore arranged for a lecture to be given in the Royal Institution, Albion Street, Hull, on Friday, January 8th, 1886, at eight o'clock in the evening, by Mr. J.

Udale of Sheffield. The syllabus comprises the following:—History (brief); Classification; Propagation; Cultivation—for Conservatory Decoration, Specimen Plants (including training Flat, Bush, Pyramidal, and Standard) Specimen Blooms for Exhibition; "Dressing;" Insects; Mildew; Select varieties for various purposes; Bouquets and Decorations.

— THE NATIONAL CHRYSANTHEMUM SOCIETY will hold an exhibition of flowering Chrysanthemums at the Royal Aquarium, Westminster, January 13th, when prizes will be offered in six classes "with the view of encouraging the cultivation of late-flowering Chrysanthemums." The classes are for twelve incurved blooms, six ditto; twelve Japanese, six ditto, twelve blooms any varieties, and for a collection of cut Chrysanthemums. The prizes, of which two are offered in each class, range from £2 to 10s. Many are curious to see what the result will be, as if a full show can be provided in the middle of January it will form a most welcome attraction at a dull season.

— A HORTICULTURAL CONGRESS is to be held in Paris from the 4th to the 9th of May next during the great International Exhibition, at which a number of topics in connection with horticulture are to be discussed.

— THE ORCHID ALBUM for December contains four particularly good coloured plates, not that the execution could be better than usual, but the subjects are very distinct. *Aeranthus Leonis* or *Angræcum Leonis*, as it is known in gardens, is well represented. The plant is a native of the Comoro Islands, at an altitude of 5000 feet, and was discovered by M. Léon Humboldt, who introduced it to Europe. It is dwarf in habit, with curved falcate leaves, and racemes of four to seven white flowers, which are freely produced. A superb plate is given of *Dendrobium nobile nobilissimum*, the grand variety which has become so famous. *Odontoglossum Insleayi splendens* is a wonderfully fine variety, the sepals and petals brown, the lip golden spotted with bright red. A faithful figure of the distinct *Miltonia Warscewiczii* is also given, the large lip being of a peculiar crimson hue with a lighter margin, the sepals and petals brownish and undulated and crinkled.

— MR. R. G. WATERMAN, Roseleigh, Woolton, Liverpool, sends the following note on THE RAINFALL OF 1885:—The rainfall in this district for the past year amounted to 34.75 inches. The heaviest fall during any one month was in October, which proved the greatest on record, the amount as registered by a 12-inch gauge being 7.30 inches. In the months of January, March, April, and August a fall of less than 2 inches was recorded. The heaviest rains of any twenty-four hours occurred on June 4th and December 30th, with falls of 1.02 and 1.10 inches.

#### THE WHITE BLADDER-BLOOM.

A SHORT time since we received from Mrs. Crowley, Waddon House, Croydon, a fine example of the fruit of *Physianthus albens*, or the White Bladder-Bloom, which had been forwarded to her from Cannes, and as the plant is little known in England we have had a woodcut prepared, showing also the flowers which accompanied the specimen in question.

*Physianthus albens* is a member of the *Asclepias* family, and was first described by Van Martius in his work on Brazilian plants from specimens which that botanist collected in the woods of Ypanema in the province of St. Paul's. Seeds were sent to this country in 1830 by Mr. Tweedie of Buenos Ayres, and the plants produced flowered freely in 1831, from which an illustration was prepared for the "Botanical Magazine" (t. 3201, 1832). A few years after examples of the same plant were sent to Lindley, then Editor of the "Botanical Register," with the statement that they had been received from Mexico apparently in mistake, as was explained when the flowers were figured in the work named (t. 1759, 1836.) In Decandolle's "Prodromus," vol. viii. page 533, this *Physianthus* is referred to the genus *Arauja*, which has been adopted by several authors since, with it being associated *A. sericea* (formerly known as *Apocynum Peruvianum*), *A. calycina*, and *A. angustifolia*, all natives of Brazil or neighbouring districts.

In cultivation the *Physianthus* has always been scarce, being confined to botanic gardens or a few private gardens where curiosities are prized. This is probably due to the fact that it cannot claim a prominent place on account of its beauty, though the white flowers possess a powerful fragrance, and when the plant is bearing its large twin fruits it is very remarkable. Like many of its relatives it is of twining habit, producing the white flowers in small stalked clusters (usually four each) from near the axils of the opposite bright green leaves. Before the corollas expand they have a curious inflated appearance, and to this it owes the generic name popularly rendered "Bladder-Bloom." The fruits are rarely produced under cultivation, and in the figures we have cited, which are the only ones known to us, this most characteristic feature is omitted from the absence of materials. When mature the fruit measures about 8 inches

from tip to tip of the two lobes, but occasionally only one of these is produced or becomes fully developed. The surface is curiously wrinkled or puckered, and when ripe it assumes a rich orange colour and is then very ornamental. It is probable that by artificial fertilisation these fruits could be more frequently obtained on cultivated plants, but as with other

#### EXHIBITING CHRYSANTHEMUMS.

MR. IGGULDEN asks my opinion as to admitting Japanese Anemones in a stand of Japanese. I write briefly to say that I should not countenance this. We must draw a line somewhere and keep to a certain stan-

Fig. 2.—THE WHITE BLADDER BLOOM, *PHYSIANTHUS ALBEUS*.

Asclepiads the method of fertilisation is strangely different from most plants, and a good idea of the arrangement of the organs can be obtained from a careful examination of one of our common hardy Asclepias.

dard for the guidance of future exhibitors. There is no mistaking the character of this new addition among the classes of Chrysanthemums. It is a distinct type, and recognised as such, by a separate class being pro-

vided for it in most schedules, so I certainly should not admit it as suggested by your correspondent any more than I should any other distinct type. Neither should I admit *Triomphe du Nord* and *Salteri* in the class for reflexed varieties. I thought it was now generally well known that *Empress of India*, *Mrs. Cunningham*, *Lady St. Clare*, and *Snowball* were all one and the same variety, and should not be allowed as distinct.—C. ORCHARD.

[We have a letter on the same subject from Mr. Molyneux which cannot be inserted this week.]

## FERNS—THEIR HISTORY AND HABITATS.

[A Paper read before the Paxton Society by Mr. J. G. Newsham of Sheffield.]

(Continued from page 587.)

IF the fibres of the roots, especially of our more robust varieties, are examined minutely, it will be observed that they form a great mass of thickly matted rootlets, the fibres being excessively numerous, and of extremely delicate formation. The roots throw out their water searchers to great distances, which render it necessary that the soil be rich, light, and unobstructive. It is therefore of the utmost importance that no cavity or vacuum should be allowed to exist, and that drainage should have special attention. Again, when rockwork is properly filled in less chance is given to snails, mice, and other pests to find lodgings. Spread a layer of soot and ashes, say an inch in thickness, on the ground. This will check the upward tendency of worms, and so prevent ravages among the fibres of the roots. Above this spread 2 or 3 inches of loose stone or broken pots, or even coke makes an excellent substitute. Next take the rough and fibrous parts of your soil, which must be all thoroughly decayed and spread over the drainage to prevent the soil being washed amongst it. I am quite aware that in most instances this simple precaution is neglected, but depend upon it, it is an important point. It prevents the upper parts of the rockery from becoming sour, and the lower parts from being soddened, thereby inducing a rapid growth of the fibres.

The foundation laid, next comes the selection of material for the structure. It would be utterly impossible for me to decide or even form any idea of what each person would fancy, but assuming that the plants are to form the chief feature of the rockery, it will be necessary to construct it in order to produce that effect. I should recommend the large cinders from our steel-converting furnaces to be used for the external parts. These may be dipped in a thin solution of cement, which will give them a much cleaner appearance. Let the interior portion of the rockery be well filled in as the work progresses. A few barrow-loads of brick ends mixed with the soil will help in keeping it open and promote a rapid growth. Being of a porous nature they will retain a certain amount of moisture to feed the fibres in case by accident the external parts become too dry. The soil must be composed of half loam and sand of a sharp nature, the other half well-decayed leaf mould. The best loam we can use is that formed by decayed sods.

Some authors recommend rich garden soil. This I consider is a folly. The richness of garden soil depends upon the amount of manure, or products of manure, which it contains at the time, and we are all aware that the richness cannot last long under constant use of the watercan. Garden soil is not, as a rule, fibrous, and therefore not suitable for the purpose. The loam I have named contains the decayed roots and remains of vegetable matter, which not only keeps sweet, but feeds the Ferns and encourages the roots to spread more freely. This when mixed with leaf soil is far more preferable than peat, because all Ferns will grow in it, whereas we find many of our British species which will not thrive well when planted in peat. For the upper parts of the rockery I should advise a variety of stone, in order to secure the geological requirements of the various species. Erect one corner, say, of tufa, which is an excellent substitute for the calcareous or limestone Ferns. Let the opposite parts be composed of sandstone, the old red sandstone if possible; this will accommodate another class of Ferns, and the centre of the upper portion pieces of rock from slate strata, or if you are not able to get this, you can easily obtain a few broken slates; stand them up edgewise a little apart from each other, and fill in with soil containing rather more sandy loam than leaf mould. Ironstone, gypsum, or grauite makes an excellent rockery for some of our smaller specimens generally found on old ruins.

In my experience of gathering Ferns I have noticed very particularly that *Scolopendriums* grow remarkably well in ironstone strata, and, generally speaking, are much inclined to sport or deviate from the ordinary type when found in these localities.

The arrangement of Ferns depends entirely upon the varieties at command.

"Plant behind plant aspiring: in the van  
The dwarfish, in the rear retired, but  
Still sublim: above the rest, the statelier stand."

In all you do try to imitate Nature. No work, however elaborate and concise, can furnish information more trustworthy and more to be copied than this great teacher. Give the Marsh Ferns, *Athyriums*, Royal, and other Ferns the moistest places. Instead of giving you a list of Ferns you may grow, it will be better to enumerate the Ferns you cannot grow on outdoor rockery—that is, those of our British varieties.

British Ferns not suited for outdoor work—*Adder's Tongue* (*Ophioglossum vulgatum*), *Bristle Fern* (*Trichomanes radicans*), *Film Ferns* (*Hymenophyllum tunbridgense* and *Wilsoni*), *Maidenhair* (*Adiantum Capillus-Veneris*), *Naked Polypody* (*Gymnogramma leptophylla*), *Shield Fern*, *Alpine* (*Polystichum Lonchitis*, or commonly called *Holly Fern*), *Maidenhair Spleenwort* (*Asplenium viride*), *Rock Spleenwort* (*A. fontanum*), *Sea Spleenwort* (*A. marinum*), *Spear-shaped Spleenwort* (*A. lanceolatum*), and the *Woodsias* (*ilvensis* and *hyperborea*).

I will conclude my remarks on this mode of growing Ferns by just referring to the supply of water. Always syringe the rockery during dry weather at night. Never water over the fronds in the morning, if you do this the sun will quickly change the beautiful green tints for the yellow brown colour which gives such a forlorn and scorched appearance. Water at night allows sufficient time to thoroughly invigorate the plants and penetrate the whole structure, thereby preparing them for the dry atmosphere during the forthcoming day. By a due observance of these simple yet really necessary precautions, you will do much towards assisting your plants to a vigorous growth, and to supplying yourself with a source of real pleasure and enjoyment.

### FERNS UNDER PROTECTION.

We come now to a very large field for thought and discourse. Immediately plants of any description are placed under protection we relieve Nature of the responsibility, and take upon ourselves an important task. All their wants, means of sustenance, remedy against evils, pests, and all other contingencies rest upon ourselves. This is not less so with Ferns in order that we may enjoy their beauties during the long dreary days of winter. The constant care and regular attention required to keep Ferns in a vigorous and healthy state often wearies the cultivator. Thus that ceaseless force must be a genuine love for the plants grown. Under all circumstances bear this great point in mind, that Nature, and not books, must be your ideal. I do not wish to ignore the great value of our books, quite the contrary. Books point to Nature, and are the keys to knowledge. Cowper says:—

"Knowledge dwells  
In heads replete with thoughts of  
Other men."

But I advise lovers of Ferns to search for them in their native haunts, and thus become acquainted with their habits, the various soils in which they grow, the moisture they require, and the natural conditions under which they flourish.

Ferns may be grown in various ways under glass—in the greenhouse or fernery, either upon the rockwork or in pots; but by far most Ferns are grown in our houses in cases or under bell shades. Nothing gives me more pleasure than to see a neat Fern case well constructed, and not too full of plants. But how often do we see the reverse. Many a time have I noticed cases of this description, presenting but poor credit, and I would fain have knocked at the door of such houses and proffered a few useful hints to enable the owner to become more successful. One common fault is overcrowding, caused often by a wrong selection of Ferns, which when planted in the new, light, and spongy soil rush away to the top of the case, filling it with a dense mass of foliage. The roots in most cases crowd the pan, devour the most nutritious portions of the soil, and, as often is the case, suffer for want of support just when you fancy you have achieved success, puzzling the owner by a sudden collapse, which may sometimes end in the case being consigned to the attic to wait further orders. Choose the most suitable varieties to begin with, say of British the following:—*Adiantum Capillus-Veneris*, *Asplenium marinum*, *A. Adiantum nigrum*, *A. Trichomanes*, *Cystopteris fragilis*, *Polypodium Phegopteris*, *P. Dryopteris*, *Scolopendriums*, and *Athyriums*. When further advanced in the art of management grow the *Filmy Ferns* and *Killarney Fern*, or *Trichomanes radicans*. Select from this list and arrange them at distances a few inches apart, some raised above

others by the aid of small cups of virgin cork or other substances, others planted openly in the lower parts of the case, while a few may be suspended in small baskets either of virgin cork or cocoa-nuts cut in half. When the plants have grown to their full size the case will not be too crowded, and the beauty of each separate Fern will be maintained. Every third season, or oftener if the plants show any signs of failing health, carefully remove them and renew the soil; thus you will continue the beauty of the case without having so often to make purchases.

Many very pretty varieties of exotic Ferns may be grown in the Wardian case, especially among the half-hardy kinds. Most Fern vendors show such in their catalogues they send out, giving the temperature required by stating their native habitat. Bear in mind that it is almost useless to attempt to grow Ferns from the tropics in these cases; they require too much heat, and never look well long together. Select such as you can from America, New Zealand, New South Wales, Tasmania, Norfolk Island, and Australia. These are the most likely localities, using, of course, care in your choice, selecting only the dwarf varieties, not by carelessness planting a Tree Fern in your miniature fernery. The inventor of the Wardian case was the late Mr. B. M. Ward of London. To him we owe the existence of so many beautiful exotic Ferns. Those from the tropics could scarcely ever have reached this country had he not contrived this mode of bringing them over. In all cases, however, they were speedily removed from their prison to the stoves at Kew and other suitable houses as soon as they arrived. The idea of adopting cases of this description for permanent homes for some of the hardier sorts was happily taken advantage of to decorate our rooms and to add to our fireside pleasures.

(To be continued.)

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 558.)

### PROPAGATION.

STRIKING the cuttings of Chrysanthemums is an important item in the growth of these plants. There are various methods practised, some finding one to answer best and some another. As most persons like to know which is not the correct way to do certain

Fig. 3.

things as well as they like to understand the proper lines to follow, I will first describe the system I have found the best, and state the reason it is so. I will also detail a few other methods which are faulty, and consequently not to be recommended.

An idea largely prevails among the inexperienced that bottom heat is requisite for striking the cuttings. This is quite a mistake, as the application of heat at this stage tends to weaken the after-growth of the plants. They should be grown as sturdily as possible, never exciting them so as to unduly draw them up, particularly in the early stages. This is an important point to bear in mind. A great deal depends upon the quality of the growths to begin with. A weakly-grown cutting can be made to improve very much, but while that is taking place much valuable time is lost; therefore select thoroughly good cuttings.

Both good and bad cuttings are represented in the annexed engravings. No. 1 (fig. 3), as can be seen by the bloom bud in the axils of the leaves, is the wrong one. This was taken from the stem of a plant. No difficulty would be experienced in striking this cutting, but the chances are that before it had grown beyond an inch or two other bloom buds would form instead of growth shoots, and sometimes no shoots are produced, so stubborn is the plant to alter its course; therefore to take such cuttings as these is sheer waste of time. No. 2 (fig. 4) is the cutting to select. It was taken at some distance from the stem of the parent plant, and gives promise of free uninterrupted growth. They should be about 3 inches long, not too sappy, and cut square across below a joint. Stout suckers find favour with some growers—namely, growths that push through the soil and taken off when about 2 inches long with bristling roots attached. This is a simple method, and the plants may be grown quite as good as from the orthodox cuttings. One

Fig. 4.

objection only do I see to the sucker system—if the stock of any particular variety is scarce it obviously cannot be increased so quickly as if a cutting is severed above the soil, leaving a portion of stem to produce further growths. Some growers cut out the buds or eyes from the lower part of the cuttings to prevent the growth of suckers in the summer. This I do not consider necessary nor wise, because the production of suckers in a proper manner does not interfere with the well-being of the parent plant, and where is the stock of cuttings to come from for another season if such strict measures are taken to prevent their growing at all?

Having explained the kind of cutting to select, I will endeavour to make as clear as possible the best means of striking them. The best of all methods is under handlights, or in a propagating frame, placed in a house having a temperature of from 40° to 50°. These should be on the side stages, and as near the glass of the roof as possible, so as to prevent the cuttings becoming drawn. If handlights are not available boards affixed in the shape of a frame with laths across at suitable distances to support loose squares of glass will suffice. These home-made appliances answer the purpose well as long as they are air-tight or nearly so. Some growers strike their cuttings in a cold frame, but my reason for preferring a cool house is that much time is often lost in a frame through severe weather. I have seen them frozen hard in the pots for a fortnight. This will not kill them, but while they are in that condition they are not making roots, therefore must be losing time; and if they are protected from frost they must be sometimes covered for several days, which renders them liable to suffer from damp. Certainly they are more checked in this position than in a house where light is not obstructed, and if they are not subjected to frosts they are less liable to suffer from damp. Some persons strike them in pots on shelves close to the glass in an ordinary greenhouse, but in such a position they often flag very much, rooting is retarded, and time lost. They ought not to flag at all. Five or six cuttings are occasionally inserted round the edge of a 4-inch pot. They strike readily enough in this way, but when the plants are potted singly they receive too severe a check by the loss of soil from the roots during the operation of

separating them. When the cuttings are placed singly in small pots no such check can occur in shifting the plants into larger, as no disintegration of the roots or soil need take place. This I consider a sufficient reason why the cuttings should be inserted singly in pots. These should be about  $2\frac{1}{2}$  inches in diameter (inside measure), commonly called thumbs. Long narrow pots are the best, as the roots strike directly downwards, and a larger number of such pots can be arranged in a given space than others of the same capacity—wider, but not so deep. The pots should be perfectly clean.

When I say never use a dirty pot some persons may perhaps imagine I am too particular about little things; but it is by rigid attention to the smallest matters that the greatest successes are won. In turning plants out of pots that were dirty when used the roots cling so tenaciously to the sides that many are broken in the action of removing them. This does not occur when the pots were clean, but the plants are shifted with their roots intact, and do not experience the slightest check from the operation. One crock in each pot is sufficient for drainage, covered with a little rough decomposed leaf soil, or, what is handier, the rough pieces taken from the soil in passing through a half-inch sieve, which is necessary in using pots of this size. Fill the pots firmly with soil, the best for the purpose being composed of about equal parts of leaf mould and light loam, with a free use of coarse silver sand thoroughly mixed. On the top sprinkle a small quantity of sand, to be carried down with a blunt dibber for the cuttings to rest on, the rooting process being quicker among sand than soil. The soil should be pressed firmly round the cutting, particularly its base, and a gentle watering given through a fine-rosed waterpot to settle the soil and sand. Stand the pots on sifted ashes for securing a cool moist foundation and excluding air. The lights must be kept closed until roots are formed, with the exception that they may be taken off for an hour in the morning for the dissipation of excessive moisture, and in the evening the glass should be wiped dry. This in the dull days so often experienced at this time of the year prevents damping. Shading will not be required. In about a month some of the cuttings will be rooted. The strongest-growing varieties are the earliest to emit roots. A little air should then be admitted by tilting the lights slightly at first and increasingly until they can be safely removed. But while some of the plants need air the leaves of others will flag. This is caused by those particular kinds not rooting quickly and strongly. These should be removed to a frame by themselves, where they can be kept closer than those which do not flag and require more air to retain that stocky growth which is such an advantage. Through keeping the frames closed little water is required during the process of rooting, yet the soil must be kept sufficiently moist for the support of the cuttings or plants.

Another method of propagation is sometimes practised by persons wishing to save space. Soil to the depth of 4 inches is placed in a heated pit or on a hotbed, into which the cuttings are dibbled, keeping them closed till rooted. In this way they strike readily, but it is a system not to be encouraged, as the check caused to the plants in transferring them to pots is too severe, and the crowding in the bed also causes them to be drawn up weakly.—E. MOLYNEUX.

(To be continued.)

### NOTES.

**PEA BLISS'S ABUNDANCE.**—I gave this Pea a trial in our orchard house early last year. I had about a hundred pots, six Peas in a pot, and fruited several good dishes from them. I found it as good, if not better, than American Wonder. Peas outdoors were not up to the average with me owing to the dry weather.

**CELERY WHITE PLUME.**—I gave this Celery a trial, but I find it will not stand the frost, and is only useful for early stewing purposes.

**POTATO EARLIEST OF ALL.**—This was very good, and of excellent flavour soon as dug. It was bought of Messrs. Laing & Co. along with the following, but was only used in the house this year. Laing's Standwell, a rough-skinned variety, also a good cropper and of excellent flavour, gave great satisfaction. For the table Cosmopolitan is also a good variety.

**GRAPES.**—I would like to hear if any of your correspondents have ever tried the experiment of grafting or inarching Gros Maroc on to a Muscat of any sort. I have a Mrs. Pince, which is not liked here, I thought of trying the Gros Maroc on this. What do some of our Grape-growing correspondents think.—A. J. B.

### THE BLACK LILY—FRITILLARIA KAMTSCHATCENSIS.

This plant is generally known in gardens as the "Black Lily," an appropriate name, as the flowers are the nearest approach to that colour of any we have seen, not excepting the wonderful black Tulips we hear so much about. It is one of those which botanists are not at all agreed about; it has been put into no less than four genera—viz., *Amblyria*

*kamtschatcense*, *Sarana edulis*, *Lilium kamtschatcense*, affine, and *quadri-folium*, and the name given above, which is that now adopted and sanctioned by Mr. Baker in his "Monograph of Tulipææ." It is the old Kamtschatka Lily of Linnaeus, under which name it is even yet found in the old gardens, where we not infrequently see large patches strong and healthy, which in a forcible way show what these bulbs are capable of doing when left alone. In the neighbourhood of London it never fails with an annual supply of bloom on a rockery having a northern aspect, and growing in ordinary garden soil. We have, however, heard of it deteriorating and finally disappearing, although our own experience is quite the reverse of this. One thing it seems more liable to than the majority of its class, although it frequently happens with *Liliums*—that is, a periodical breaking up of the larger bulbs; but although this takes place and it seems by no means regular, there are always a few large bulbs capable of flowering left to the next year. This may in a measure account for the deteriorating, and disturbing the bulbs by digging to see what is the matter may very readily complete the operation. If grown near stones not deeply embedded in the soil, they should be carefully watched, as the bulbs seem to have a tendency to run to the sides and underneath the stones, when we may get a glimpse of the foliage, but never any flowers. From its hardy nature this is one of the bulbs that should never be missed from a collection of hardy plants, as it will give as great satisfaction on a partially shaded border as on the rockery, the latter not always so easily attainable as the former. It grows from a foot to 18 inches high, the lanceolate leaves being in whorls much the same as in the old Martagon Lily. The flowers are bell-shaped, drooping, several in a head, of a deep shiny maroon black, with pretty golden stamens. It flowers in July and August. Native of Kamtschatka, Siberia, Japan, N. America, and California.—D.

### KITCHEN GARDEN.

In our directions for the coming season vegetables for exhibition as well as for home use will receive attention. Great county shows, and others of that character, often draw exhibitors from a distance, and these generally showing high-class produce set an excellent example to others; but village and parish shows were never so plentiful as they are now, and as fresh exhibitors are constantly arising, hints which will help them to increase the size and quality of their produce will be given in this column.

**TOMATOES.**—Early fruits of these are always valued. As a market crop they are very profitable, the price at any season is never unremunerative, and in early spring it is always good. The earliest fruit is to be had from plants raised from cuttings. Where these were put in during last October the plants ought to be placed in larger pots at once; use a mixture for them consisting of three parts loam and one part rich manure. Give them moderate drainage, and pot firmly, afterwards placing them in a temperature of 60° or 65°. Here they will soon commence growing rapidly, and the side shoots should be taken to form more cuttings. These will make fruiting plants sooner than any which can be raised from seed, but where no plants exist seed-sowing must be resorted to, and the first batch should be sown at once. Two dozen plants or so will make a good hatch for early work, and to raise this small quantity the seed may be sown singly in 3-inch pots. Use rich soil, and place in a temperature of 65°. Keep the plants near the glass, and do not supply too much water until they have plenty of roots. Short sturdy growth is the kind to secure at this season, and particular attention must be given to growing them full in the light and near the glass. Last year we had a few old Tomato plants left in their fruiting quarters at the end of December. Early in January these were trimmed in and cleaned, then a rich surface dressing was added; growth soon began, and they produced ripe fruit sooner than any of our young plants.

**FORCING.**—Hotbeds should now be formed with the materials which have been collected for them. Make them firm, so as to retain the heat as long as possible. They must be at least 3 feet in height at the back and 2 feet at the front, and be 1 foot wider than the frame which goes on the top of them. Some time ago we had a long range of frames made, 4 feet 6 inches in height at the back and 3 feet in front. The fermenting material is put inside until within 10 inches or 1 foot of the top, soil is put on the surface, and Potatoes are planted in this with good results, the advantage being that the manure is all under cover and not exposed to the weather like an ordinary hotbed. The heat is retained for a long time in this way, and our early Carrots, Radishes, &c., are all produced in quantity from frames of the kind indicated. Sbarpe's Victor Potato is a good one for present planting.

Early French Horn Carrot is the best for first crop, and French Breakfast Radish "bulbs" better than any of them in February and March. Attempts are often made to grow a mixture of Potatoes, Carrots, and Radishes in the one frame, but the plan is not commendable, as none of them ever come to any great degree of excellence, and a very inferior sample of all is the general result. We never saw Asparagus force so

profitably as it is doing this winter. Place more roots in heat to keep up a succession.

Cover more Rhubarb and Seakale; forcing will become easier daily, and those who have been holding back until the turn of the year may proceed at once. We find a few early dishes of the things named give great satisfaction in the kitchen, and although roots might prove a little more remunerative further on in the season, the produce will not be so much valued then. Keep up a constant supply of Mustard and Cress by sowing both every ten days or so. Sow a large hatch of Cooling's Ne Plus Ultra Kidney Bean. The seed will soon germinate in a temperature of 65°, and the plants will bear heavily in March. In forcing these, as well as everything else, it is an advantage of the greatest importance to have the young plants in the full light and close to the glass. Where frost has been severe, Lettuce and Endive may have been injured, and the supply of salad in February and March may be curtailed, but where there is plenty of Chicory or Witloof roots in the open they may be made to form a good substitute if lifted in quantity, potted in groups, and placed in a dark corner where the temperature is from 60° to 70°.

**BROAD BEANS.**—A good sowing of these can now be made on a south border; Early Longpod is a very desirable variety. A rather heavy soil suits them best. We do not find Broad Beans much valued in summer, but a few dishes very early are always relished, and it is to secure these we advise sowing now.

Digging, trenching, and manure-wheeling should be pushed forward. All empty spaces in our garden are now turned up, and this in suitable weather we find facilitates operations considerably at sowing and planting time. Where there is a regular staff of kitchen garden hands work of this kind generally receives timely attention, but in smaller-sized gardens it is apt to be neglected until the last, when there is a great rush to dig and sow on the one day; and although this practice may answer in the case of some crops it is by no means a good system. Seed lists are now coming to hand daily; we always order early, with the object of having all the seeds at hand when they are wanted, and everything that is wanted for the season is got in at the same time. Standard varieties should be depended on and dealt with for main supplies.

#### FRUIT FORCING.

**VINES.**—*Early-forced Vines.*—Early-started Vines as a rule look very promising, having made good progress considering the weather. Those started gradually always produce more compact bunches and make better progress than when forced hard during the dark weather generally prevailing in December. Young canes that have been suspended over fermenting material should be tied to the wires as soon as the most backward buds have pushed freely from the rods. Disbudding must be gradually proceeded with, and young growths should be tied down before they touch the glass. Stopping is a matter of great importance. Some growers stop one, others to the third or fourth joint beyond the bunch, but where the Vines break and grow evenly we consider it preferable to stop them to the third or fourth joint beyond the bunch provided there is space at command, and after this allow the laterals to extend until sufficient wood is obtained to cover every available part of the trellis with fully developed foliage, when the strongest growths are again stopped to prevent overcrowding. As the bunches become prominent the house may be kept a few degrees warmer, or 60° at night, and 10° to 15° warmer by day from fire heat, or 70° to 75°, to 80°, with gleams of sunshine. Where fermenting materials are used on inside or outside borders attention must be paid to the temperature, which will not vary much where the border has been kept well covered with dry fern and shutters up to the time that a body of dry warm Oak leaves was substituted for the fern.

*Houses to Afford Ripe Grapes in June.*—The house must now be closed and the inside border supplied with water at a temperature of 90°. Syringe the rods twice a day with tepid water, taking care to wet every part of the buds and wood, allowing the night temperature to range from 50° to 55° on mild nights, and 60° to 65° by day with sun; but if the weather be cold and dull 55° by artificial means need only be maintained. As a means of saving fuel introduce a good heap of Oak leaves, to which one-third of short stable manure has been added; turn it frequently, and make additions as the heat declines.

Fruiting Vines in pots placed in or over fermenting materials may be kept warmer and drier as the bunches come into flower. Tie down and stop young growths, and afterwards allow them to grow until every part of the trellis is covered with foliage. Select thoroughly ripened wood for eyes, and insert in pots or sods at once; if for growing into fruiting canes no time should be lost in getting them into heat.

*Late Grapes.*—These must now be cut without delay, in order that the Vines may be pruned, cleansed, and allowed to rest. It will be advisable to dress the cuts with styptic, and when the Vines, glass, and walls have been properly cleansed the inside borders should be cleared of all exhausted mulching, and top-dressed with a thin layer of turf, loam, crushed bones, and rotten manure over all. The outside borders that have been covered all the winter may also be exposed to the influence of the weather, leaving a slight covering only of litter to keep out frost.

**CUCUMBERS.**—Plants must now be prepared for the early spring supply of fruit. All things considered, there is no variety equal to Rollisson's Telegraph for every purpose. The seeds may be sown singly in 3-inch pots, in a rich light mould, leaving room for top-dressing the plants when they require it, and plunge in a brisk bottom heat near the glass, and cover with a clean piece of glass, which must be removed as soon as the plants come up. Maintain a genial atmosphere with a night temperature of 65° to 70°, or 5° less in cold weather, running up to 80° or 85° with sun, putting on air at 75° just a little, to insure a change of

atmosphere, being careful to prevent a check by a sudden cooling or drying of the atmosphere. Tying, thinning, stopping, and arranging the shoots must be attended to as occasion requires.

**MELONS.**—Plants from seed sown now will give ripe Melons by the end of April or beginning of May, contingent of course on everything going on satisfactorily, and the weather is favourable to their growth. The seed should be sown singly in 3-inch pots, in fine loam and leaf soil, leaving room in the pots for top-dressing when the plants require it, plunging them to the rims in a hotbed made of fermenting materials and covering them with a pane of glass, which must be removed as soon as the plants appear through the soil. When they have made a couple of inches of growth they should be top-dressed, keeping them as near the glass as practicable without touching it, to prevent their becoming drawn. Should the frame be found full of steam when it is opened in the early part of the day, it will be advisable to provide ventilation at night to allow of its escaping, otherwise the plants will damp off. Where there is a Cucumber house or a fruiting Pine stove, the pots may be placed on a shelf near the glass with a piece of glass over them, and then danger from damp will be obviated. In the matter of varieties, Davenham Early, Scarlet Premier, Eastnor Castle, and High Cross Hybrid are excellent.

#### PLANT HOUSES.

*Soils.*—Work in the various plant departments will soon be abundant, and every opportunity should be taken to place under cover the various soils needed, and to prepare them for use. Fibry loam being the staple soil for the majority of plants, a good stock should be placed under cover without delay. The heap of soil outside, if properly stacked at first and in a suitable moist condition, will be so at the present time, except, perhaps, a few inches of the outside, which may be rather wet. This, if well intermixed with the remainder, will be suitable by the time it is required for use. We frequently, however, keep this separate, and place it in the warmest and driest position in the shed, turning it once or twice before placing it with the main heap. It is a good plan to commence at one end of the stack, chopping it down from the top to the bottom, and by this means the turves are partially broken up, and in this condition they are placed under cover. This soil is then chopped as fine as required for potting purposes, on wet days or when other outdoor work cannot be done. After chopping we pass a good heap through a coarse sieve and remove all the soily particles, which is ready without further trouble for cuttings and other operations for which fine soil is required, the rough and fibry portions being placed in a heap for those plants that enjoy a loose open soil. It is surprising how rapidly the work of potting proceeds when a good stock of soil is ready for warming at any time when required, or to be placed direct upon the bench.

*Peat.*—This is much better outside, where heavy rains can be thrown off it until required for use, than in sheds and other positions where it will become dry. A good supply should now be wheeled in a shed and broken up at the first opportunity. We usually obtain two kinds of peat—the one for Orchids, and the other of a harder nature for hardwooded plants. The last is broken up with the hand, and all Fern and other similar roots removed, the fine being left with this heap as broken up. As the work proceeds any pieces of an inferior quality are placed on one side, both out of this kind and that used for Orchids, to be afterwards broken and used for Ferns. The Orchid peat is roughly broken, and the whole of the fine removed by passing it through a sieve. Peat fibre, from which all the soily particles have been removed, lasts in good condition double the length of time that it does when broken into lumps and the fine used with the fibre. The fine removed from this peat is always very useful for mixing with other soils to fill small pots in which the cuttings of many stove plants are rooted. It is also very useful for seedling Ferns as well as many other plants.

*Leaf Mould.*—For plant-growing leaves in a half-decomposed state, that have never been heated by being thrown into a heap, are decidedly the best. The leaves we use are scattered over an enclosed space in a small wood, and are frequently turned over by fowls; the layer of leaves is only about 14 inches in thickness, and never becomes heated. This is passed through a half or three-quarter-inch-mesh sieve in the yard, and all that does not pass through freely is left behind. A good quantity is placed under cover, and when mould in a finer state is required it is passed through a finer sieve when wanted for mixing with composts.

*Manure.*—In addition to the refuse of old Mushroom beds, which is principally used for Fuchsias, Caladiums, Begonias, and other similar plants, we rely entirely upon cow manure for all plants grown in pots. The manure to be used during the spring has been in a cool shed since the end of October, and stacked outside for some months previous. The supply for summer and autumn use is stacked outside, and will remain until room can be found for it under cover. The manure now in the shed is in capital condition, and before use is passed through a quarter-inch sieve. A good heap is sifted ready for use, but the majority was required. Those who have none under cover should get some in at once, or else it will not be in good condition for potting purposes. If very wet place it in baskets, or spread it thinly where it can be gently dried. Care must be taken that it does not become baked. When most of the moisture has been removed so that it will pass through a sieve, it should be placed in a heap in a cool shed and another lot dried. Bonemeal is very useful for potted plants, and the required quantity should be obtained ready.

*Wood Ashes.*—This in the compost for many plants is very beneficial, and all prunings should be laid together until a fair heap has been collected and then burnt. The ashes should afterwards be passed through a fine sieve, so that all unburnt portions of wood can be removed. The ashes should then be placed under cover and kept dry. Where wood

ashes cannot be obtained, soot mixed in the compost will answer the same purpose; in fact, we have principally to rely upon the latter, for we cannot get sufficient ashes for our requirements.

## THE BEE-KEEPER.

### PROSPECTIVE MANAGEMENT.

BEFORE the busy period is upon us it will be wise to consider the system that is likely to give most satisfaction both in the light of economy, profit, and securing suitable stocks at the end of the season. To those who are already supplied with hives no advice is necessary; but to those who are contemplating bee-keeping for the first time a little advice may not be out of place. Premising that all such have studied the hives most suitable to them, be they of straw or of wood, if the former are to be selected, let them be well made and of sufficient size. Efface from the mind the absurd idea that a hive suitable for one district is unsuitable for another. Intending bee-keepers should become fully impressed with the great importance of having nothing but full-sized hives, and of one uniform shape, in their possession.

Where frame hives are to be selected, we advise that preference be given to those put together by mortice and tenon before those that are nailed only. Simple single-cased hives, either nailed or dovetailed, if attention is paid to protecting them thoroughly from sun and wet by the use of some cheap material which may be gathered by the wayside, will give as satisfactory results as the most expensive hive made; and if a number of expensive hives I have had occasion to examine for a company of bee-keepers are a fair sample of others, cheap ones as above will give a great deal more satisfaction. The cardinal point to be observed in making cheap hives is that they be of one size outside measurement, so that they will fit into outside cases, which from their utility in bee husbandry will be found more easily managed than double-cased ones.

The locality alone must decide which is the better—the swarming or the non-swarming system. In some districts the honey season expires with the advent of summer; in all such places the non-swarming system should be strictly adhered to. But in districts where the season extends from the end of April till the end of September, then the swarming system will be found to be most profitable; yet to keep up the working powers of the top swarms till the end of the season it will be absolutely necessary to supersede the old queen by a young fertilised one within three weeks after hiving. By carrying out the swarming system thoroughly it will be necessary to have two-thirds more hives than are required for stocks during the winter, which adds considerably to the expenses of the apiary. By carrying out the swarming system thoroughly in a good district, and with a prolonged fine season, the yield of honey would be very great, as it is, indeed, in some parts of Lanarkshire, where it is carried out to the letter. But our variable climate sometimes puts a stop to “the best laid schemes” of the apiarian, and the yield of honey is almost nil, and better results would have been obtained had at least a portion of the hives been prevented from swarming. Nay, if the average of the past fifty years be taken it will be found that from the non-swarming hives the market has had the greatest supply of honey. It is with the bee as it is with other rural pursuits—controlled by the weather. The want of foreknowledge of what the weather is to be prevents us acting with any degree of certainty, but he will display his wisdom best who makes preparations, so that no chance will be lost, working and acting upon the principle that “a bird in the hand is worth two in the bush.”

There are districts, too, where the honey does not appear till August. To allow bees to swarm in such districts would be folly, or to divide them artificially during summer, and have to feed until the honey season appeared, would be a

case of “the cost o’ergoun the profit.” I am of the opinion that taking one year with another, and keeping the cost of extra hives in view, which must be kept if the swarming system is rigidly carried out, in the majority of cases the non-swarming system will give the most general and greatest satisfaction. The doubling of swarms will also be satisfactory, but in no case should a queen of the previous year be depended on till the season is advanced, but she should be deposited after it has been hived. The success of the apiary under any system depends greatly on the raising of young queens. One hive for every ten kept will be sufficient for raising the young queens required for keeping up the population of the hives.

The foregoing remarks will perhaps assist those not sufficiently experienced in apiculture as to justify them adopting a course which might turn out a ruinous one so far as profit is concerned. But before closing let me remind the youthful apiarian that though a capacious hive lessens the risk of swarming it does not prevent it. Swarming in many cases occurs with but partially filled hives. Young queens, in conjunction with large hives, are the best preventives against swarming. In all cases of lessening the size of the full-stocked hive let that be by removing supers only. The practice of lessening hives (unless weak ones) during winter might, for any good it does, be dispensed with. Certainly, large hives as a rule have both more empty and full combs. The former are doubtless in appearance more congenial to the bees, while there are always plenty of the latter within easy reach at all times, and which are termed “blocks of ice” by those who recommend crowding the bees into as little space as possible during winter, which by that very act leaves the bees without an alternative but to sit on what they characterise as blocks of ice! How often do we see bees located in the roofs of houses having an unlimited space, and yet do well too after severe winters! For some years now my hives have stood without the slightest contraction during the whole season, and nothing but benefit has accrued from the treatment. If kept thoroughly dry the bees are more rested during winter in a large hive than in a small and crowded one.—A LANARKSHIRE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

Robert Veitch & Son, 54, High Street, Exeter.—*Catalogue of Kitchen Garden and Flower Seeds.*

Harrison & Sons, Market Place, Leicester.—*General Seed Catalogue for 1886 (illustrated).*

W. Leighton, 89, Union Street, Glasgow.—*Catalogue of Garden Seeds.*

George Bunyard & Co., Maidstone.—*Catalogue of Vegetable, Garden, and Flower Seeds.*

William Paul & Son, Waltham Cross.—*Catalogue of Vegetable and Flower Seeds.*

Frederick Roemer, Quedlinburg, Germany.—*Catalogue of Flower and Vegetable Seeds.*

J. Butterson, Hammonton, N.J.—*List of Small Fruits and Evergreens.*

\* \* All correspondence should be directed either to “THE EDITOR” or to “THE PUBLISHER.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Privet and Fowls (R. H. J.).**—We are not aware that the leaves of Japanese Privet are poisonous to fowls. Birds eat the fruit of the common Privet with impunity, and the leaves have an astringent bitter taste. We have seen fowls bask under Privet hedges, and have not known any injurious results accrue from the birds pecking the leaves. If the experience of any of our readers differs in this respect we will readily publish it if communicated.

**Leeks (Tomlinson).**—It is difficult to form even an approximate estimate of the weight of a market bunch of Leeks, as early in the season there are only eight to ten in a bunch, while later there are fourteen to sixteen. You can now form an estimate as well as we can.

**Alterations (An Old Subscriber).**—Your having made the alterations to which you refer previous to the passing of the Agricultural Holdings Bill you do not come under the Act in question. If you are in trade as a nurseryman you can remove or sell your stock-in-trade, including the glass structures, on the expiration of your tenancy. The payment of rent determines the character of your tenancy in the absence of any written agreement. A six-months notice of quittance on either side suffices, to terminate at the time you took possession of the premises.

**Eradicating Weeds and Moss (Constant Reader).**—A quart of a pint of sulphuric acid mixed in a gallon of water and immediately poured upon the path will destroy all small weeds, so will an ounce of crude carbolic acid in the same quantity of water. A waterpot with a fine rose answers best for the work. Care must be taken not to let the acid touch the clothes or boots, or it will burn holes in them, and it will also kill Box or Grass edgings. Apply it in fine weather, and you will have no more weeds for several months. The acid can be had from any chemist or oil and colour dealer.

**Boiler and Pipes for Cucumber House (An Old Subscriber).**—The boilers you name and others similar are suitable for heating a Cucumber house. You will need four rows of 4-inch pipes for top heat, and if you have the fruit early you will require pipes for bottom heat, two rows on the flat under a bed 4 feet wide, the pipes 1 foot from the sides, surrounded and covered with rubble to a depth of 6 inches, and above this you will need a space of 12 inches for soil. If you have the bed we should only have two rows of 4-inch pipes close to the front for top heat, and have the other two at the side of the bed towards the interior of the house, or on the brickwork forming the edge of the bed.

**Temperature for Vines at Rest (F. J.).**—The temperature ought not to exceed 50° from fire heat whilst the Vines are at rest, but 40° to 45° is sufficiently warm for greenhouse plants by artificial means, and is the temperature that ought to be maintained. A valve ought not to be used for regulating the heat from the boiler unless there be more than one structure heated from the same boiler, then valves are necessary. What you seem to require is a damper so as to regulate the heat of the furnace, and consequently the heating of the water. Your boiler is too powerful or too hard stoked. Keep less fire, and regulate the draught by the ashpit door. Sixty is very much too high for Vines at rest, and is very prejudicial to greenhouse plants in winter. It is in fact a forcing temperature. Keep at the temperature named above. Coke is a preferable fuel for your description of boiler, breaking it small.

**Watering Vines in Winter (Merchant).**—As the inside border near the water pipes is "very dry," by all means give water copiously at once, and do not let the soil get so dry again. It is quite immaterial whether you remove the surface-dressing of manure or not. Probably you can moisten the border more effectually by raking it off, pointing up the surface of the soil lightly so that the water is evenly distributed, then replacing the manure. Possibly one watering may be quite inadequate, and two or three copious applications may be requisite; in this case the last may be with liquid manure if you have reason to think the soil has become impoverished. It is quite safe to water Vine borders in winter, danger lurking in allowing them to remain dry; and liquid manure, if it be needed, may be given with equal safety when Vines are resting as when they are growing. You may plant your Roses at any time when the weather is mild and the soil in a dryish, free-working condition. They may be partially pruned, removing a third or so in length of the shoots, pruning more closely in March or after fresh growth has started.

**Besi de Quessoy Pear (T. W. G.).**—The above is the name of your Pear, and it has seven other names. The following is the description in the *Fruit Manual*:—"Beside de Quessoy (De Quessoy; Besi de Caissoy; Poire de Caissoy; Petit Beurré d'Hiver; Roussette d'Anjon; Nutmeg; Small Winter Beurré; Winter Poplin).—Fruit produced in clusters; small, roundish, and fattened at the apex. Skin rough, with a yellowish green ground, but so covered with brown russet as to almost completely cover the ground. Eye open, set almost even with the surface. Stalk half an inch long, stout and thick, inserted in a pretty deep cavity. Flesh white, delicate, tender, buttery, with a rich aromatic and sugary flavour. A small dessert Pear, ripening in succession from November till March. The tree attains a good size, and bears abundantly as a standard, but does not succeed well on the Quince. The original tree was found growing in the forest of Quessoy, in Brittany. It is a very old variety, and is mentioned by Merlet.

**Stakes for Trees (Prince).**—The best we have used are of Larch, the young trees or the tops off them thinned from crowded plantations and divested of their side growths. We have found these to last longer than Oak, or any other wood, probably because of the turpentine in the Larch. Creosote is a good preserver of wood. It can be had from chemists, and should be used hot, the end of the stakes being placed in an iron vessel containing it over a fire and boiled. Some persons dip stakes in molten pitch, and others char them by inserting their ends in a fire for a time, then withdrawing them and slaking with water. This is a simple and good plan when well carried out; but whatever method may be adopted of preserving the wood it must be applied not to the points of the stakes alone, but 3 inches above the part inserted in the ground. Stakes decay more rapidly quite close to the surface of the ground than several inches below. We have been told that stakes soaked in petroleum are rendered additionally durable, but we have not tried it.

**Planting Anemones and Ranunculi (X. Y. Z.).**—Choose the first fine day when the soil works cleanly for planting your Anemones. They are best

planted in the autumn, but will do now. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties, a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted, cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up, by observing the side that has the old small fibres on it. That side place next to the bottom of the drill. When all are planted and covered up the right depth (2 inches) then level the surface with a garden rake. The soil and preparation of the bed you describe will suit them very well. Ranunculi will all probably succeed if you mulch the bed in the spring to keep it moist, but they prefer stronger soil. The season for planting is in the early spring, as soon as the most severe frosts have passed and the ground has become tolerably dry. Some time about the end of February or the first week in March, rake the surface of the bed in the morning of the day previous to that fixed upon for planting. Some recommend steeping the roots for twelve hours in water before planting, but we think this not necessary, except the planting season has been from some cause or other put off till the middle of April; then it may be useful. Supposing, then, that the weather is propitious, and all things prepared, commence by drawing with a hoe a drill across the end of the bed, 1½ inch deep; if deeper the roots will be weakened the succeeding year, by forming a kind of stem nearer the surface; and if shallower, the plants are more liable to be struck with drought. Plant the tubers, if large, 4 inches apart in the row; if small, 3½ inches will be a sufficient distance, and cover them with fine sand. This will cause the tubers, when they are taken up in July, to come out of the ground quite clean for keeping.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (*Pomo*).—The Apple Noir Binet is not grown in England under any other name. The American Apple has been called King of Tomkins County, but we do not think it is that variety. It is not easy to name foreign varieties from one specimen only.

#### COVENT GARDEN MARKET.—JANUARY 6TH.

Market quiet. Supplies falling off, with a better demand for good samples of Grapes.

## FARMING PROSPECTS IN THE NEW YEAR.

As the old year passes away and the new year opens before us we reach a period of time when events of the past and present are passed in review, and due thought is given to measures for the future. Well indeed would it be if past lessons could be so turned to account as to give point and certainty to future work; but, alas! we still have the agricultural depression upon us, and although there are some rays of light which give promise of a better state of things, yet there remains enough of doubt and uncertainty to bid us be cautious in all we do, and to take no steps either upon old or new lines without well considering the end.

A leading question much discussed during the past year, and which is still far from being settled, is, Can we afford to continue the culture of Wheat in this country? Yet the answer is simple in the extreme, and really merges into the answer to the wider query, Can we compete with the markets of the world, opened as they are to corn merchants by free trade? If land cannot be had at a rent proportionate to the price of Wheat it cannot be cultivated profitably, and therefore a reduction of rents is inevitable, and, so far as we can judge, such a reduction will be permanent and not temporary. With vast tracts of land under the fine climate of many of our colonies, with the great and ever-increasing facilities for carriage by land and sea, and the keen competition for freight between rival carrying companies, the farmers of Great Britain are put very much upon a level with those of that Greater Britain, as our colonies are sometimes inclusively termed. If, however, landlords bow to the inevitable, and rent is reduced, it certainly is the farmer's duty to do all that is possible with the land. We do not advocate extremes, but taking good sound common sense as the foremost qualification desirable in a farmer, we may assert that to practical knowledge he must now add sufficient scientific culture to enable him to obtain all the help he can from mechanics, entomology, botany, vegetable and animal physiology, chemistry, and accounts. Lamentable is the ignorance still to be found among farmers. It was only a week or two ago that we were told in open market by a man holding two large farms that cockles in Wheat was a mystery—a thing of seasons, coming and going in a manner inexplicable, that much Wheat had been badly affected by it last year! Yet the youngest of our pupils could have told him better. We have no faith in so-called mysteries, and science is fast sweeping away all the nonsensical ideas which have so long been handed down from one generation to another, and have in reality often been a source of serious loss.

Manual and horse labour will, and, in point of fact, are fast being reduced, every improvement in machinery and implements being a step in that direction. A few intelligent labourers with a thorough technical training will sooner or later take the place of the many old-fashioned illiterate labourers. Well has it been said recently that "Times have changed, and the farmer now requires fewer hands, must be far higher in intelligence than in the past."

Another important matter is the general wish to avoid those leeches who live upon the very life blood of farmers—the middlemen. There can be no doubt that advantage has been taken of Barley discoloration to press low prices upon the farmer, yet the price of malt to the consumer keeps high. Bullocks have fallen so in price that there is a loss rather than profit upon all inferior animals. Sheep, too, have also been very cheap, yet our butchers' prices have been sadly out of proportion. Fitful efforts have been made by several farmers to alter this, and we may mention one remarkable

example of recent occurrence. Colonel Briggs of Hylton Castle was only getting 4½d. per lb. for sheep, yet his labourers were paying 9d. per lb. to the butchers for mutton. By having sheep killed and sold to the labourers at 6d. per lb. he got 15s. per head more for his sheep, while there was a saving of 18s. per head going into the pockets of his men. Butchers' profits of 50 per cent. afford sure proof that in this as in many another case middlemen make far more profit than is justifiable. Middlemen are shrewd keen men of business—altogether too sharp for an easy-going farmer of the ordinary type. One farmer or a dozen cannot grapple with such an evil; there must be sensible combination to protect common interests, and it has been suggested that this is a matter for the serious consideration of our leading agricultural societies.

Trial stations, an extensive and ever-growing knowledge of the elements of plant food, pointing to an economical application of manures; pure seeds of the best sorts, an abolition of fancy prices, more general energetic action, more intelligence, and much less of paying money to middlemen for doing our work, and in many an instance cheating us. Bags of mystery are those wonderful compounds termed special manures, which are pressed upon us in such a tempting form, done up neatly in bags bearing the flourishing impress of the dealers' designations. How is it possible that a farmer can rest content with so unsatisfactory a state of things? Can he afford to purchase so-called manure adulterated with 50 per cent. of dust? Can he afford to purchase cattle food in the form of oilcake, that so frequently proves not only to be largely adulterated, but to be positively injurious to the animals it is given to? Can he afford to pay 1s. per lb. for mixtures of grass seed containing a large proportion of seed of inferior sorts not worth half the money? Yet he has done and is doing all this, and if the years of heavy depression serve only to eradicate all such grave faults, such loose practices, from farmers as a class, it will prove a blessing rather than a curse.

It may be that in this paper we have wandered somewhat from the literal meaning of our title, and instead of pointing out prospects and probable results, have dwelt rather upon matters affecting farming prospects. Yet these are all things pressing for careful attention, and we would once more press upon our readers the importance of intelligent inquiry into cause and effect, never resting satisfied with a vague imperfect understanding of what is passing around them, but striving for clear knowledge of everything affecting their work. With increasing knowledge will come that humility and teachableness that is not at all incompatible with self-respect. It will lead to better practice, better results, and will tend as much as anything can do to bring to them, as we heartily wish it may, a Happy New Year.

## REMARKS.

27th.—Fog early, fine and bright after, foggy at night.  
 28th.—Dull and showery, with intervals of sunshine; evening wet and windy.  
 29th.—Bright and cold throughout, snow showers in evening, frosty night.  
 30th.—Bright and cold morning, dull after, with slight fog; wet evening.  
 31st.—Dull, warm, and hazy throughout, shower about 2 P.M.  
 Jan. 1st.—Dull and damp all day.  
 2nd.—Fine and warm.  
 A dull and rather damp week, with a good deal of mist and fog. Temperature slightly above the average.—G. J. SYMONS.

### HEATING AND PROTECTING.

**W**INTER has come, to London at least, in a manner that cannot be mistaken. The earth at the time of writing is shrouded in snow, and no one knows how low the mercury will fall in the thermometer in twenty-four hours; and if it rises, as it may do suddenly, it would be very unwise to assume that the winter is over. So proverbially changeable is our climate that gardeners ought never to be taken by surprise. They should always be prepared for a variation of 50° in the daily range of temperature. If there is no such difference all the better; but the fact that the range is often considerably greater proves the possibility of its re-occurrence. The direction of the wind, the character of the clouds, the movements of the barometer and thermometer, should all be observed thoughtfully; then generally, but not always, the nature of the weather can be anticipated during the coming eight or ten hours, and in this case no great extent of mischief need be done when means are afforded for its prevention. It is when the means are at hand and not applied that there is so much cause for regret not only for injury that may be done, but for the disquietude of mind that either is or ought to be endured on the part of a delinquent, as there cannot be a doubt of its existence in the minds of those who have in a great measure to trust to others for the execution of important duties.

Young men especially should be on the alert against weather surprises, and should never leave their post of duty so long as a doubt remains as to a safe method of procedure. By an hour's indulgence he had no right to claim, the character of a man for trustworthiness may be lost, and will assuredly be hard to regain. Indeed, the prospects of many a steady, industrious, but somewhat indolent and unobservant youth have been destroyed in a night or an hour. He may have retired too soon or rested too long, and the mistake has influenced prejudicially his whole career.

It is not in times of peace that soldiers win honours and promotion. It is in troublous times that their qualities of watchfulness and endurance are tested. It is precisely the same with gardeners—young men who are entrusted to a great extent with the success or failure of the “coming campaign.” Early forcing and bad weather are the opportunities for gardening students to distinguish themselves, and the earnest, attentive, and thoughtful do not fail to turn them to account. Keeping out frost in one case, and keeping up the requisite heat in another, are matters in which no man should permit himself to fail if they are within the bounds of possibility.

A great secret of success is in taking pride in the work in which it may be a person's duty to engage—not in that part only that can be most agreeably performed, for in this neither effort nor sacrifice is required, but in the less fascinating but not less important portion of his duties. It is perhaps quite natural that many young men should delight in furnishing artistically and satisfactorily a drawing-room jardinet, and if this is part of their work they ought to deter-

mine to excel in it; but unless such men take equal pride in the orderly and thoroughly workable condition of a subterranean stokehole they are very seriously at fault, and their shortcomings will sooner or later tell seriously against their advancement. If a person make himself trusted for doing well the work that is out of sight he will not be very likely to neglect that constantly under inspection. “Once upon a time” I was told on good authority that when a gardening appointment was made which many coveted, an individual was selected mainly because the stokehole in his charge was found to be in such perfect order. It was considered that a person so careful and systematic underground not only permitted no waste there, but was not likely to fail on the surface. Experience justified the soundness of the reasoning.

A well-managed stokehole should be always “fit for company.” A clean floor, clear ashpit, free bars, with doors, dampers, valves, clean also, and in perfect working order; and another matter, not sufficiently attended to, should never be overlooked—a clean boiler. Not only should no obstruction be permitted in the flues, but not the slightest incrustation of soot should be allowed on the boiler. Even an eighth of an inch of carbonised matter there will involve the consumption of as much fuel for its penetration as would heat all the water in the apparatus. These are not the days for wasting fuel. Boilers well set and the connections good act well or the reverse according to the way the former are managed, and many an apparatus, good in itself, has been unjustly condemned.

The competent man—he who maintains the requisite amount of heat with apparently little trouble, uses as a rule much less fuel than one less successful with the temperatures and who rushes about and blazes away as if he were doing the work of two or three men. When the work of such an one is examined it is certain to be faulty in some of the points indicated; and in another thing he fails, and it is a far too common occurrence—he starts too late in the afternoon and not soon enough in the morning. A thousand head gardeners who will read these notes know that to be true.

A house of winter Cucumbers may be taken as illustrative. The temperature at ten o'clock at night ought we will say to be 65°, falling a few degrees, but not below 60° at daybreak. The day proves bright, and the sun, with heat in the pipes, raises the temperature before midday to 80° or 85°. In the afternoon it commences falling, and the thermometer registers 75° at three o'clock or a little after, and in half an hour it falls to 70°. By that time the pipes are cold, or nearly so, and the fire is started; but before the water is appreciably heated the mercury falls to 65°, and is still descending, reaching 60° by 6 P.M., if not sooner. In the meantime an almost frantic endeavour is made to arrest the fall, fuel is thrown on, stirred to consume it as rapidly as possible in producing fierce flames; if half a pound of candles are handy in they go, or half a pint of petroleum—anything to raise the temperature. And all this excitement and attendant waste is caused by not starting the fire soon enough. The moment the temperature from the sun decreases that of the pipes should commence, and increase steadily to check any sudden fall—in fact, the fire should be the master half an hour before sunset, then the fall to the ten o'clock minimum can be regulated to a nicety, with much less than half the consumption of fuel that is required to “raise” the heat that ought never to have fallen so low. This mistake of not starting fires early and gently is not only wasteful but often dangerous, because very frequently it ends in overheating at midnight, and the air of the house becomes so parched as to be inimical to the well-being of the plants.

Starting the fires too late in the morning is a practice equally to be reprehended because equally wasteful and injurious. If the attendant is at his post at six o'clock, or sooner if needed, to stir the fire and prevent the temperature falling below the daybreak minimum, he is master of the position, for if the day promises to be dull he can easily raise the tem-

perature a few degrees by nine o'clock, while, if bright, he meets it with moderately heated pipes; but, on the contrary, if the fireman runs with half his clothes on, and boots unlaced, at seven instead of six o'clock, and finds a temperature of  $55^{\circ}$  instead of  $60^{\circ}$ , fierce firing at once commences to raise the heat, and just when the pipes are "burning hot" the sun is on the house and the plants are between two fires. The heat cannot be kept down except by extreme ventilation, and this cannot be afforded without drying the atmosphere of the house and inciting such extreme transpiration from the foliage that renders it peculiarly inviting to the attacks of red spider; and no one can grow Cucumbers or anything else well, and red spider too. Heating is a very important matter, and the secret of success may be expressed in three words—be in time; economy then goes hand in hand with efficiency, and this combination is a credit to the man by whom it is achieved.

So much, but not too much, having been said on the subject of heating, there is little space left for that of protection, and it must suffice to say that not half enough attention is given to preventing the radiation of heat from glazed structures by the use of blinds. Fire is used, and must be used to produce heat, but as a rule slight endeavours are made to conserve it. Blinds are necessary in summer to keep the heat of the sun out of houses, and for that purpose are extensively employed; but while they might be still more profitably used in keeping the heat in the structures in winter, it is very seldom we find them thus saving fuel and maintaining an equable temperature. In nurseries, and especially on the continent, where it is necessary to practise the most rigid economy, blinds are drawn over glazed roofs during cold nights in winter, as well as on hot days in summer, but there is no such general practice in private gardens. If blinds can be supported an inch or two above the glass instead of resting on it, they are more effectual both in summer and in winter.—EXPERIENTIA DOCET.

### THE FUTURE OF GARDENING AND GARDENERS.

MR. TAYLOR having thoughtfully hoisted the gardeners' flag of distress, we should, I think, be lacking in courage and circumspection if we did not carry it round, exhibit it to our friends and neighbours, asking their opinions and advice, so as not only to discover what are the real causes which have led to our forlorn condition, but also be able the better to realise not only what our present position is, but also what are our future prospects. The question "What is to become of our great private gardens and our army of professional gardeners?" is at this time very suggestive and pertinent, but is not very easily answered.

That private gardens, with a few fortunate exceptions, are at the present time under a heavy cloud is unquestionable, and while that cloud overshadows them the gardeners' position must remain either unchanged or become even worse than it now is. The very fact that the garden and the chief part of its products are not essential luxuries to the wealthy classes, although they may be their greatest, as they are also their most wholesome and enjoyable pleasures, is sufficient cause why the garden should in unsettled and adverse times be the first to suffer for want of support. For gardens and gardeners to flourish it is highly essential that the commerce and trade, as well as the agriculture of the country, should be in a thriving and healthy condition. Bad seasons and depression in agriculture, however, are not of themselves sufficient to account for the continuance of this overhanging cloud at the present time, but there are greater, wider, and in some respects more deplorable causes, which I imagine are not proper subjects for introduction to your columns.

It may, however, be said with safety and propriety that the wealthy classes, as a rule, are not niggardly when times are flourishing, when landed and other property is comparatively secure, and when there are no disturbing influences prejudicing their future stability. At the present time it is not money probably that is so much required as it is, let us still venture to hope, the temporary absence only of that good old English feeling of kindness and good will towards each other, that genuine feeling of friendship between the upper and lower classes, for which England in the past has been so distinguished, so justly proud, and which has undoubtedly contributed in no small

degree to her prosperity, as well as to her proficiency in the science to which we are devoted. In times of difficulty like the present masters in their perplexity are too apt to place undue pressure on those whom they have engaged to occupy positions of trust and responsibility. They somewhat unreasonably demand equal, or even increased results at considerably reduced expenditure, and the outcome, as Mr. Taylor infers, is too often failure, in which the gardener is comparatively the greatest sufferer, because he not only frequently loses his position, but too often that also which is of more value to him, his character as a gardener. This cause of annoyance to the master, and most deplorable termination to perhaps, in many instances, a long and honourable service on the part of the gardener, might often be avoided if the master would only exercise a little more judgment, discretion, and self-sacrifice, by permitting a portion of the most unprofitable and expensive part of his garden to be converted, for the time being, either into woodland, game cover, pasture, or to any other purpose which might be deemed most convenient and profitable.

On the other hand, the gardener's bounden duty is to readily conform to altered circumstances, and endeavour by every means in his power to carry out his master's instructions, instead of, as sometimes occurs, foolishly and uselessly combating what he conceives to be the erroneous determinations of his employer. It is the acknowledged privilege of those who "pay the piper to choose the tune." This line of action must, I think, be right because it is reasonable. "As to what is to happen after the next move or two in the same direction," as Mr. Taylor significantly puts it, I know not. I would rather say, "Sufficient for the day is the evil thereof." True prophets are very rare in these days; even our greatest philosophers, who have essayed to foretell coming events, have been but false teachers. Let us, therefore, not suppose by looking on the dark side only that the next move or two will be in the same downward direction, but rather let us hope and believe that they will have an upward tendency, that better times are coming. After the storm comes the calm, after the cloud the sunshine. It is not the first time even in my recollection that gardeners have had similar trials to endure, although I must admit the present trial is a painful one, and must surely prove a severe check to the progress of our ancient profession; but that the day will come, I trust soon, when with the revival of trade and agriculture, when with a better understanding between master and servant, when a better and more united, a more affectionate feeling will be manifested between all classes throughout Great Britain and Ireland, when everyone will be induced to look rather to the performance of his duties than to the possession of that which he conceives to be his rights, when the servant will be more content with the position which Providence has assigned him, and when, on the other hand, the master will be less selfish, less exacting, less suspicious, more considerate, more just to those in his employ; when also, by the passing of judicious land laws, the owner and the occupier will each feel safe to invest his capital with ample security, and with every confidence that it will be safe from the intrigues of misguided agitators—then, and not till then, I fear, will gardening and gardeners again flourish with increased vigour.

There is no lack of taste for gardening, but the very opposite is the case, and while this continues to be so it will eventually revive. Unfortunately there are great numbers of excellent gardeners and young journeymen at the present time who are by this lamentable depression thrown out of employment, as every nurseryman throughout the country can testify, many of whom are unfortunately simply existing rather than living, and for their sakes it is very desirable that gardening should revive.

Never was there a time, perhaps, when the necessity of a Gardeners' National Relief Fund for the unemployed was more felt than it is at the present. Had but the wise and timely suggestions which emanated from the generous heart of the late Mr. T. Speed some years ago, when at a Manchester show, been then actively and generally adopted, when gardening was in a flourishing condition, there would have been at the present time an accumulated fund sufficient to have met the immediate and pressing wants of our unfortunate brothers. It does seem strange that professional gardeners have never combined generally to form a special fund similar to that mentioned. While every other trade and profession have some such organisation, gardeners, although from the peculiar nature of their calling they should be far-seeing and provident, and although they are acknowledged as a class to be fairly intelligent, temperate, prudent, and generous, yet they have hitherto failed to combine nationally for each other's benefit. It is true there exists the "Gardeners' Royal Benevolent," the "United Horticultural Benefit," and other local societies, but the funds of these excellent institutions are wholly or chiefly intended to benefit the

aged and infirm; they do not give that help which is now so much needed, nor form that connecting link between active professional gardeners of all grades and ages which is so desirable, especially in such unfortunate times of depression as the present. The only hope of a discharged gardener now, unless he be possessed of means, of which there is but slight chance, is on the nurseryman; and although these gentlemen have always shown the greatest sympathy towards gardeners in distress, still in times of depression like these they cannot do impossibilities nor find employment for all; the consequences are, I am grieved to say, many cannot find suitable situations, and are often reduced to very painful circumstances. Experienced gardeners are sometimes compelled either to comply with most miserable and unjust conditions, or else undertake elsewhere such service or work for which they are totally unfitted, and they unfortunately sometimes lose courage and self-respect, hope gives place to despair, and they sink deeper and deeper in the social scale. How many of these there are who with a little timely help, such as an institution like the one suggested might have afforded, could have been kept from sinking, perhaps started in a small but suitable business, and thus been enabled to gain a decent living instead of being reduced to semi-starvation. I must apologise for this lengthy and somewhat gloomy epistle at the commencement of a new year, but knowing that your columns are always open to any suggestions intended to improve the gardener's position I venture to send it, sincerely trusting the dark cloud will soon pass away, and that the new year's sun will quickly shine with more brilliancy on gardens and gardeners than has that of the past year.—T. CHALLIS.

### ROSE MILDEW—NOTES ON GYPSUM.

ABOUT a year ago there was a discussion in your columns on Rose mildew, and I suggested that gypsum should be tried as a remedy. If anyone else has tried this it might do good if they would state the results, whether adverse or beneficial, so as to see whether it is worth using. We are all learners. For my own part I have been almost free from mildew on Roses, but would not like to say it is due to the gypsum unless the fact was corroborated by others.

It may perhaps be interesting to state the results when applied to other plants as a manure. I gave a dressing to all the usual kitchen garden crops, but could see no difference in those parts of the rows where it was applied than where they had none. The same with Gooseberries. Where it was given to young Black Currant bushes they did not seem to grow so well.

The most remarkable effect was on a bed of Gooseberry cuttings. As far as the gypsum went a great many more of the cuttings died than where it was not applied. It was seen quite easily to a few inches how far it had gone. The extraordinary fact was that where the gypsum was sprinkled over the ground after the cuttings were inserted it was most hurtful, although it was not in such proximity to the roots, but where it was dug in before the cuttings were inserted it did least harm. With Red Currant cuttings in the same place it had no bad effect, there being scarcely a blank where the gypsum was in the soil and where they had none, notwithstanding the very dry season, and when we dug some up the roots appeared to revel in it.

Where the gypsum was sprinkled over the ground I frequently noticed that the ground looked damp as if it had had a shower, when elsewhere it was dry. Knowing that gypsum was supposed to yield moisture in dry weather I rejoiced over this, thinking that the gypsum had an affinity for moisture, and drew it from the atmosphere, and that it would be beneficial to the Gooseberry cuttings, as the summer was so dry. I now think that it must have subtracted moisture from the ground, which had a contrary effect.

**SNOWDROP POTATO.**—On the recommendation of "A Kitchen Gardener," vol. x., p. 167, I planted this new variety of Potato, and can endorse all that he said about it. It is a heavy cropper of first-rate quality, has shallow eyes, is of good appearance, very floury, and of a beautiful white colour when boiled. I did not find any diseased tubers among them. It is a second early kidney. What more can be desired?—W. KRUSE.

**P.S.**—I have been trying twenty-four varieties of Strawberries for three years, in order to see which are the most profitable, &c. If you thought it desirable I would send you the notes I have taken on them the last two years if I can find time to arrange them.—W. K.

[We shall be glad to receive the notes obligingly offered.]

### CELERY CULTURE IN NOTTS AND YORKSHIRE.

CELERY-GROWING within the last seven years has become quite a business in North Notts and South Yorkshire. In the neighbour-

hood, within a radius of ten miles of Bawtry, 25 acres of land sufficed for the crop in 1878; but during the past year, 1885, upwards of 400 acres were devoted to Celery. The variety grown is called the Clayworth Pink; it was raised in the village of Clayworth, and is a most excellent sort, being good in most kinds of soil. The land in the parishes of Everton and Hayton where Celery is grown is peat or bog; in the parishes of Clayworth, Wiseton, and Gringley-on-the-Hill the land is strong loam. Peat with a clay or cool subsoil answers better for growing Celery than stronger land. Most kinds of crops exhaust the soil—Celery improves it. The second year is better than the first, and so on—that is to say, the land requires less manure the third year than the first, and is much easier worked. Celery taken up the first year weighed  $2\frac{1}{2}$  stones per bundle of twelve roots, and after seven years' cropping the weight per bundle of twelve roots is  $4\frac{1}{2}$  to 5 stones, sometimes more—not merely one or two bundles, but row after row as taken up. The land where this is grown is peat with a clay subsoil.

The seed beds are prepared in January and early in February. They are made of leaves and manure, or any kind of heating material which is at hand. When the beds have settled frames are placed on, and 6 inches of good soil is spread evenly over the bed, which is well watered and allowed to remain for a day or two. The seed is sown thinly over the surface, and covered with a little fine dry soil, and gently pressed in with a smooth board. The

Fig. 5.

frames are then closed until the seed begins to germinate. The time for sowing is from the last week in February to the end of March. Great care is taken to make the beds quite flat—this is to say, the same height at the front as at the back, so that in watering the seed is not displaced by the water running from back to front, which frequently causes the seedlings to damp off. When the plants have made their second leaves they are given plenty of air to harden them ready for pricking out in the open when they are strong enough to handle. Beds of 4 feet wide are prepared by forking in short manure, which the roots adhere to and form small balls of soil, when they are taken up to be planted in the trenches. Women are employed to prick them out at 6d. per thousand. Quick women can earn from 2s. to 2s. 6d. per day. The plants are dusted well with soot once or twice or more if the weather is showery during their growth in the beds.

This acts as a fertiliser, and is effectual in keeping off the fly. Planting out in the trenches is commenced early in May. The trenches are made 5 feet apart. They are opened out with the plough and finished with the spade. Manure is spread in them from the cart and forked in 3 or 4 inches deep. The planting is done while the land is moist. The plants are put in with a spade or trowel down the centre of the trench. If the weather is dry they are well watered, then mulched with litter, long grass, flags, rushes, or anything suitable that can be collected to save labour in watering. When the plants have grown 6 or 8 inches a one-horse plough is run down each side the rows to loosen the soil, then follow two men, one on each side of the row, with an implement each, called in this neighbourhood the "Push-up" (see fig. 5); the soil is pressed up from each side at the same time. This operation is performed several times during the season. The plants are never allowed to break away. The final earthing is finished with spades. The earliest crops are ready for taking up the first week in September, and realise from 2s. to 3s. per dozen roots retail price. The crop is worth from £55 to £60 per acre; often more for very good crops. Later crops from £35 to £45 per acre. The number of plants required per acre is £16,000. Cost of labour in producing earliest crops on the ground:—Average rent from 35s. to £2 per acre; rates, taxes, and tithe, 10s. per acre; manure, £9 to £10 per acre; labour, £10 per acre; carting to stations, £4 per acre; leaving a profit for the best early crops of £28 to £32. For late crops labour is £2 less, bringing a profit of £10 to £20 per acre. There are some failures, which is generally in the first year.

The average quantity sent away weekly is 200 tons from various stations in the neighbourhood. Celery-growing in this district has been a success. Several labourers, very poor men, have started with small plots and worked them in early morning before their ordinary day's work began, and in the evenings with the assistance of their wives and children. These men have now, some one horse and cart, and others two, and grow from 2 to 5 acres each. This season the Rev. W. Metcalf, vicar of Everton, has kindly assisted them

by dividing some of his field land into small plots to start them.—  
C. M. BREWIN, *Bawtry, Yorkshire.*

## FRUIT AND PLANT HOUSES.

(Continued from page 560.)

THE fittings of houses are of more importance than many imagine. Foremost are the means of bringing the plants up to the glass, which are of three kinds—viz., trellises, beds or shelves, and stages. Respecting the trellises little comment is necessary, as the plant itself will determine the distance the trellis should be from the glass, as, for instance, *Stephanotis* may be 6 inches, *Roses* 9 inches, *Peaches* and *Figs* 12 to 14 inches, and *Vines* 16 to 18 inches. Some cultivators might complain that these are too close to the glass, alleging that the nearer we bring the foliage to the glass the more we expose that to the vicissitudes of climate. But experience proves that the more we take the plants from the glass the more we encourage growth, long-jointed and sappy, large but thin leaves—everything, in fact, but a floriferous and fruitful growth. Therefore I conclude that the nearer we bring the foliage to the glass, consistent with its not touching, the more likely are we to secure thoroughly solidified growth. Wire trellises are now almost exclusively used, and being galvanised or painted answer perfectly. Some object to galvanised wire as inducing gum or canker. I have had some experience of it, and find no evil consequences attend its employment either under glass or outdoors.

Beds are only necessary when it is deemed advisable to employ bottom heat either by means of fermenting materials, hot-water pipes, or hot-water tanks. Bottom heat, however, is not now employed to nearly so great an extent as formerly, but most cultivators agree that some plants require it; indeed, it is only counting failure in attempting to grow *Pine Apples*, *Cucumbers*, *Melons*, and very early *Figs* in pots without bottom heat. Most cultivators are agreed that a bed of fermenting materials is highly conducive to the health of the plants whether placed in it or not. As a means of keeping down the fuel bill I strongly advise a bed of fermenting *Oak* or *Beech* leaves to be made in each structure where there is a central bed, and necessary for bringing the plants up to the light in all houses required to kept at a higher temperature than that of a greenhouse. The depth ought not to be less than 4 feet, and if put in soon after the new year it will keep its heat until natural conditions are more favourable.

Hot water as a means of affording bottom heat is excellent, and may be employed in three ways. First, the pipes may be fixed not more than 2 feet apart, and so disposed as to allow of at least 6 inches depth of rubble under and over them, into which the heat can pass and be retained. This depth, or about 18 inches, I consider proper; more is a waste of heating power, and less dangerous from over-heating. Secondly, the pipes may be enclosed in a chamber, which ought not to be deeper than 1 foot, the pipes being kept clear of the bottom and of the covering material, whether it be wood or slates; and, thirdly, by pipes in a tank containing water so as to cover them. This latter mode is perhaps the best, as we have heat combined with moisture, provided means be taken to prevent the soil becoming sodden, as may be effected by having 3 inches thickness of rubble placed over the covering of the tank. The tank mode of affording bottom heat is similar, only instead of the water being heated by hot-water pipes the water circulates in the tank, entering at one end and passing out at the other, the tank being divided into spaces about a foot wide by bricks on flat and about 2 to 2½ inches depth of water in the tank. This mode of affording bottom heat is not nearly so much employed as its merits deserve. Shelves, which differ but little from beds, or only in having no enclosed space beneath for means of affording bottom heat or holding soil, are, I consider, best formed of slate. I have them an inch thick, with 2-inch edges to contain material for standing the pots on, as gravel, &c. For houses where there is a considerable amount of moisture, wood shelves are not suitable, as they so soon decay.

In the matter of stages there is nothing to equal red deal properly seasoned. *Oak*, however, answers very well, but is much dearer, as also is *teak*. I have some of pitch pine, but not sufficiently long to express an opinion of them as compared with red deal. The stages should be open—i.e., laths with spaces between. I prefer them an inch thick, 2 inches wide, and fixed so as to allow an inch space between each. The wood should be dressed—i.e., planed, and be given two coats of paint before being put together, and all joints well primed with white lead. It is no use expecting the stage to last if the joints are bad, for only let water get in and the stage will soon need renewal. Two coats of paint should be given after fixing, and allowed to become thoroughly hardened before the plants are introduced.

Moisture is an essential of plant life. The means to insure it are chiefly dependant on manual operations at frequent intervals by means of sprinkling available surfaces, or even syringing; but means of affording it constantly and in proportion to the artificial heat are resorted to in evaporation troughs. These are considered necessary by some, whilst others consider them more injurious than otherwise. I do not wish it to be understood that I consider them necessary for plants not requiring more than a greenhouse temperature, but I do hold a moist heat to be at all times more favourable to vegetation than a dry one. I consider, therefore, that unless the evaporation pipes or trough are small, and the pipes are highly heated, they are useful. I have used them without any injurious effects, and I must say with marked advantage as compared with the results obtained from structures where there were none. If the house has to be kept at a high temperature by greatly heating the pipes, then shallow troughs will give off too much steam; but even in this case troughs that cause the pipes to be surrounded with water are useful, as they reduce the heat of the pipes and radiate the heat from a large surface at a much lower temperature, whilst the moisture is not relatively abundant. Besides, I find evaporation troughs a ready means of charging the house with ammonia, the troughs being filled as occasion requires with liquid manure. Similar results can be obtained by damping surfaces at intervals; but as we have moisture in Nature proportionate to the heat when vegetation makes most progress, so in the application of artificial heat we should act upon similar principles.

Material may be also used which will give off moisture and something else. Plants always do best on a moist or what we term a cool bottom, on a bed of ashes in preference to a stage or a dry slab, and they do better on a slab, be it stone or slate, than on a lattice stage. This clearly is a consequence of the moisture given and watering being in part at least retained and given off again in the shape of vapour or moisture. The value of this is apparent when liquid manure is used in that passing the pots being given back in vapour form to the atmosphere, and if we have a receptacle beneath for holding the water that passes through the pots in watering we find the plants thrive very much better than when it is allowed to run off through open stages and be lost in the soil or drains. It saves many dampings and is very much better, as the evaporation is in proportion to the atmospheric conditions, therefore more regular and better suited to the plants. We must admit the value of mulching inside fruit borders, and beds of spent tan, or even sawdust and cocoa refuse as plunging material, as they not only contain moisture, but in decomposing afford some nutriment. In shading I need only remark that except for such plants as *Ferns* fixed shadings are not good; smearing roofs with whiting and skim milk, or even summer cloud, and everything that obstructs the light constantly, I do not recommend. What we want is a material that can be put on and taken off at will, for which I know nothing better than the roller and canvas shading with laths to keep it from the glass, and allow of ventilation under any circumstances.—G. ABBEY.

## CHRYSANTHEMUMS IN THE NORTH.

It seems to be generally admitted by all that the past season has been anything but a good one for the "queen of the autumn," and it seems a question whether growers in the north or those in the south have suffered the most. Certainly northerners have had to contend against one of the dullest and most sunless seasons on record; and although some collections may have had to the uninitiated a pleasing appearance through the months of August and September, inasmuch as they "looked healthy," still they have not come in well at the "finish;" indeed, in more than one case have we heard of collections (and some that looked well in the months named) failing to bloom at all, and in several cases where good attention had not been given the blooms have only been very indifferent. We have really felt sorry for some amateurs who have this season for the first time made an attempt. It has been very discouraging, for in some instances which we know of, in spite of enthusiastic effort, there has scarcely been a bloom to reward them. This may, perhaps, somewhat puzzle dwellers in the south, as in most cases there the scorching weather which they experienced in August gave the growths sufficient solidity to bloom, although we understand that they were a long way short of what they were in the season of 1884. On the other hand, as mentioned by Mr. Iggulden, we quite escaped injury from the early frosts, and although our blooms were from three weeks to a month late we have been having the benefit of them for Christmas and New Year's decorations, and welcome they have been. Indeed in our own case, judging from appearances at present, we shall not be long without *Chrysanthemums* during 1886, for we have at the present time plants of *Hero* of *Stoke Newington*, *Princess Teck*,

Madame Moulise, James Salter, Guernsey Nugget, Fair Maid of Guernsey, Dr. Macary, Triomphe de la rue des Chalets, and others, the buds of which are only just showing colour. Of course the majority are terminal buds, and we cannot expect them to be as good as in November and December; but how useful they are in January and February! One seems to value a few plants of Fair Maid and Madame Moulise at this season very much indeed, and always feel sorry when the last bloom has gone. However, by striking early cuttings and taking crown buds we have the much-admired and deservedly popular Madame Desgranges, with its golden sport, and others in bloom again in July or early in August (last year it was September). We hail with especial pleasure many of the recently introduced Japanese, blooming as they do a month or so in advance of the general collection. These, it appears, are the varieties which are disappointing to Mr. Iggulden, which I can quite understand. However, "it is an ill wind which blows no good," and if some of these are too early for the south we welcome them in the north.

But to return to the subject of ripening the wood of Chrysanthemums. If we were never convinced of the importance of this before, surely this season in the north has impressed it upon us; more particularly has this been noticeable in the case of the July-struck plants, which in other years we have valued so much and found so useful. This season, though struck about the same time and promised well, have in most cases entirely failed to bloom. We at first thought that had we struck a month earlier that the case might have been different, but upon looking them over we saw some plants which we remembered were put in in May and the "crown" bud taken, but still the case is much the same. A neighbour who usually grows these small plants well had this season what we considered a remarkably promising batch, but which has not turned out any better than our own. Then, certainly in this case, we must blame the season, and such statements as those which appeared a couple or three years ago as to the non-importance of ripening the wood will not do for northerners. It may do better in the south.

This leads us to the time for inserting cuttings. We are convinced that good blooms here cannot be depended upon from spring-struck plants. We insert cuttings of most varieties as soon as we can get them after the first week in November, but would warn beginners against coddling these plants in any way. We believe in the cold frame after they are rooted if not before.

With regard to Golden Queen of England refusing to properly incurve, we experienced the same difficulty, not only with this variety, but with others as well, especially the Empresses. Perhaps Mr. Molyneux or some other experienced grower will give us a little light on the subject, for, to say the least, it is disappointing. In conclusion, is there any distinction in Mrs. Marsham from its so-called parent Elaine? or is the one a counterpart of the other? I cannot see any difference.—W. JENKINS, *Aldin Grange*.

### DWARF TOMATOES.

A CONSIDERABLE number of growers are under the impression that if dwarf plants are required they should be propagated from cuttings, but this I do not consider the best plan, as I have frequently proved that the dwarfiest, sturdiest, and most prolific plants are those raised from seed in the manner here described. There are but few sorts naturally dwarf in habit, the only one included in most catalogues being the old Dwarf Orange-field, and even this may easily become tall if badly treated. It is still one of the best both as regards free-bearing and the quality of the fruit, the only fault to be noted is that these are rather too small to please everybody. Carter's Perfection I have grown in pots for several seasons and find it very prolific, and the fruit handsome and fairly large, are of excellent quality. Sutton's Perfection is rather too vigorous and succeeds better on trellises or walls, in which positions it fruits freely and continuously, requiring less heat in winter than the majority of varieties I am acquainted with. Hackwood Park Prolific can be made to produce exceptionally heavy crops on pot plants, and the fruits are large and handsome, though these do not ripen so thoroughly as they should do, and on the whole the quality must be said to be disappointing. Dedham Favourite is of good habit, being sturdy and prolific, but it is of the greatest value for open-air culture. Trentham Early Fillbasket was to have eclipsed most other varieties for pot culture, but I cannot speak very highly of it; in fact, I am not certain what are its characteristics, as each time I grew it there were several forms or sorts from one packet of seed. Earley's Defiance is a profitable sort, and Conqueror a heavy cropper. Hathaway's Excelsior is still one of the best, and although one of the earliest of American introductions it appears to be the only one that has attained a lasting popularity. Of the foregoing I can most strongly recommend Dwarf Orange-field and Carter's Perfection, while if a third variety is required

I would add Earley's Defiance, this being a good form of Large Red—one of the oldest and heaviest cropping varieties in cultivation.

In order to secure an early crop from plants in pots, in advance perhaps of heavier and later crops from those planted or fruited in boxes and larger pots, no time should be lost in sowing the seed. This should be sown thinly in pans or pots well drained and filled with fairly light soil, the seeds being only lightly covered. The soil being fairly moist, no water need be given; otherwise give tepid water through a fine-rose pot. If the pots or pans are plunged in a brisk bottom heat, or failing this are stood as near the hot-water pipes as possible, the seeds quickly germinate, and then the dwarfing process must at once commence, for dwarfed pot plants must generally be if they are to be profitable. Directly the seedlings are clear of the soil the pots or pans ought to be either raised on the hotbed so as to well expose them to all the light possible, or else stood on a warm shelf near the glass. It is also advisable to thin out the seedlings where at all crowded, this all tending to keep the reserved plants more sturdy, and, besides, it is unwise to raise many more than are really required for that particular batch. When the seedlings are in rough leaf—that is to say, have partially developed a second pair of leaves, the time has arrived for potting them off, a few days' delay adding, maybe, as many inches to their length. Any light soil suits them, the usual mixture being two parts turfy loam to one of leaf soil or thoroughly decomposed manure. This ought always to be warmed before using, and which is most easily accomplished by plunging one or more hot bricks into the heap for a short time. The potting should also be performed in the house where the plants are growing, or otherwise a severe check may be given them. There are plenty who first pot off singly into 3-inch and even smaller pots, but I am still of opinion that it is much the best plan to either pot off singly into 5-inch pots or in pairs in 6-inch pots, and can safely assert that these do not become nearly so drawn and spindly as do those in small pots, even if the latter are given a shift prior to their transfer to the fruiting pots. Directly plants either in small or large pots become root-bound the top growth soon loses its sturdiness, and by the time this has been recovered dwarf fruiting plants will have become impossible. The process of first potting must be again alluded to, as this also affects the dwarfing process. Clean pots should be used with one crock in the bottom, this being covered with a little rough manure or turf, and the seedlings should be sunk into the soil so as to bring the seed leaves, after the soil is jarred down, in preference to hand pressing, just on the surface. A little water of the same temperature as the house may be given after the pots are either plunged or stood on the bed, or else stood in a warm position where they may be lightly shaded for two or three days. They will soon commence rooting afresh, the buried stems also freely emitting strong roots. As soon as they will bear the full sunshine they ought to be well exposed to it, and as near the glass as possible without exposing them to cold draughts of air. In this manner the requisite sturdy plants will be secured, and these should be transferred to the fruiting pots before they become badly root-bound.

We generally use 12-inch pots for the single plants, but if the positions favour the use of larger pots these are made to hold two plants. Very little drainage is needed, and instead of so many crocks we find it preferable to use the roughest portion of the compost—this, I ought to add, consisting of two parts of turfy loam to one of slightly decayed horse droppings, also well warmed as above advised. We pot deeply so as to allow plenty of room, or say fully one-quarter of the depth, for a good top-dressing later on. A strong stake from 3 to 4 feet in length is at once placed to each plant, and all are then stood on a well exposed wall or staging. The balls being properly moist when shifted into the fruiting pots, no water will be needed for two or three days, but they should be examined frequently and watered carefully as required till such times as the roots have taken strong possession of the new soil, when they should be watered in the usual manner, and never at any time with water lower in temperature than the house in which the plants are growing. The first bunch of bloom will in most cases have been observed when the plants are finally potted, and on the preservation and development of this depends the character of the plant. If the work has been carried out as described, no severe check will be given, and a strong bunch of bloom will develop most probably within 12 inches or, at the most, 15 inches of the pot, and to this two more strong bunches will soon be added, which if good "sets" are obtained will yield an ample crop. From the first all side shoots ought to be kept closely rubbed out, this naturally encouraging the formation of a stout stem and extra fine foliage. The fruit does not always early in the

season set so readily as wished for, and to encourage free setting a rather drier atmosphere than is usual in ordinary forcing houses should, if possible, be maintained for a few days. Then towards mid-day, or say after a little air has been given for a short time, a smart tap may distribute the pollen and effect the set, or, in order not to risk failure, the camel-hair brush may be used for touching over the blossoms, and we have frequently effected good sets by gently rubbing the fertilising parts of two flowers together. It is not advisable at any time to syringe the plants; while temperatures that will grow them quickly are 55° to 60° by night, 65° to 70° by day, raising 10° higher with sun heat, closing the house early so as to raise the heat fully 10° higher. I give those figures as being suitable, but they may be varied according to circumstances, Tomatoes succeeding and taking "pot luck" in either Cucumber and Melon houses, or vineries, Peach, and plant houses.

I am not an advocate of starvation treatment of Tomatoes, and in pots especially liberal treatment must be given or the crops will be light. Directly the first bunch of fruit is set we give the plants a good top-dressing of loam and decayed stable manure or horse-droppings in equal proportions, and take particular care that this top-dressing of fresh unoccupied soil does not mislead us. This may be moist enough, but the fully occupied soil underneath be injuriously dry, and unless this is guarded against a great check will be given. Then if extra good crops are being perfected the plants receive later on yet another slight top-dressing of manure, and also an occasional dusting over the surface of the soil with Beeson's or some other artificial manure, this being varied with moderately strong supplies of farmyard liquid manure. From the foregoing it will be seen that we spare no pains in our endeavours to secure heavy crops of fruit, but I hold that without extra good house accommodation it is quite necessary that such pains should be taken, and, further, that the results amply compensate. I suppose that high prices for Tomatoes will never again be realised, owing to the fact that the supply has increased to such a wonderfully rapid extent. Immense quantities are now annually eaten in various forms in this country, but it is doubtful if pot culture will prove sufficiently remunerative as of old unless exceptionally heavy crops are obtained.—W. IGGULDEN.

## FERNS—THEIR HISTORY AND HABITATS.

[A Paper read before the Paxton Society by Mr. J. G. Newsham of Sheffield.]

(Continued from page 9.)

In closing my remarks on culture I would ask you to be most careful in the administration of water. Water should not be given over the fronds. The moisture in the case caused through evaporation is quite sufficient to supply all that is necessary for them. Small fountains, miniature falls, and other such adornments are useless unless the water is disposed of independently, and not allowed to pass through the soil or deluge the fronds. In the winter months supply water very sparingly to the roots, as however good the drainage the danger remains the same. Ferns grown in cases, or under close confinement in any way, are remarkably delicate, being very susceptible to mildew, and also more liable to the attack of disease in its various forms. Ventilation in a great measure depends on circumstances and the class of Ferns being grown. A little experience will suffice to teach what is required.

### THE FERNERY.

In order to fully appreciate the beauty of Ferns and to enjoy their attractions, you require to possess a properly constructed fernery. This is beyond all doubt the one ambition of the Fern fancier. In the fernery you can grow from the smallest to the largest, humour the most majestic, nestle into snug corners the very smallest, produce fair specimens of the many varieties equally as well as if Nature herself had nursed them. 'Tis here, and here alone, that you can enjoy the real sweets of this favourite pursuit. The fernery may be constructed entirely of rockwork, or suited only for pot culture simply at the will or fancy of the grower. If you wish to produce show or specimen plants adopt the pot. If artistic effect is the object, then, of course, simply convert the outdoor fernery into rockwork under protection; in that case you may add the great majority of British Ferns, all the half-hardy varieties with Selaginellas or Mosses if you think proper. Generally speaking, follow the instructions given previously, paying more attention to the composition or geological arrangement, as that will introduce a greater variety.

Objections may be raised to this method in a fernery. It has its advantages and disadvantages. Effect is the most salient feature in its favour. Again, you have certainly less trouble

with rockwork on account of the almost unlimited supply of moisture at the roots, which have a free run amongst our stones and soil, and do not therefore require that constant attention, unless it be in the matter of snails. Every night take a candle or lamp, and diligently search for the thieves, give no quarter, but destroy every trace of them; failing this you will soon find that copying Nature in part only is a disadvantage.

Ferns grown in pots require daily attention, especially in hot weather. If once allowed to get dry the plants generally suffer for the whole season, and very frequently during the one following. In many of our tufted varieties, during the autumn months, you will find the crowns forming their next year's supply of fronds. The plants will present a fullness or swelling just above the soil. If even at this period of the season you allow them to suffer for want of water, you will well understand that their progeny, from this very cause, is to a great extent annihilated. Another precaution must be taken against too much moisture. You will often find that the holes at the bottom of the pots become choked from various causes, and the water prevented from properly draining away. The results of this catastrophe in nearly all cases prove fatal unless great vigilance is exercised. Upon rockwork this rarely occurs. When plants are grown in pots they can be removed from one position to another, just as their requirements demand, whereas upon rockwork they necessarily become stationary. Constant removal of plants by taking out their roots destroys their vitality and weakens their progress in every way. I have tried both methods, and find much to admire and much to praise in each. The only advantage to me is that by growing Ferns in pots I am able to produce better specimens for exhibition. The labour is greater beyond doubt, and the achievements more difficult, but the result compensates for the extra trouble. To secure success in pot culture, you also require great judgment in potting and repotting. I have seen plants with very good prospects for their future growth spoiled by being kept in pots too small. On the other hand, a great fault is committed by our potting—that is, giving too large pots.

It is of the greatest importance that there should be a free motion of the earthy molecules forming the soil in the pots. To obtain this your pots must be perfectly clean inside; if the pores are blocked before you put the plant in, the air cannot chemically and easily combine with the soil, the salts so necessary to the plant can never be produced. It is possible to have both inside and outside clean before you remove a plant, and it is highly beneficial.

Upon the subject of watering I have said a little in respect to the various modes upon which I have dwelt. I know that in respect to overhead supplies there is much diversity of opinion. I will give you my idea and leave you to accept it or reject it.

All Ferns grown upon rockwork, whether indoor or outdoor, are certainly benefited by being syringed. Ferns in pots should be watered by the can for two reasons. First, it is safer. You might, perhaps, force a lot of water overhead, and think the plant would have sufficient, whereas a close examination of the soil would reveal the poor roots almost baked, and take it for granted that if this were allowed to continue long you would have no fronds to water, or what were left would be brown or yellow, and no doubt you would at once say syringing did it; nor would you be very far wrong either, for if you had used the can and not the syringe you might have saved your plant. Secondly, I believe that when water is given overhead to a thirsty plant it has a tendency to hasten its decay. Plants grown in windows in pots should every now and again be well washed with the syringe, or they have no chance of inhaling the atmospheric support they require. Instead of moisture they get dust and smuts.

Liquid manure I rarely use. I look upon it as teetotallers look upon beer. It may be—in fact, I believe it is—useful when given to a plant which is sickly; but even then it must be very weak. If the Ferns thrive well, let well alone. I have tried water with lime for one class, water which has been poured over leaf mould, or peat for others. In fact, I may say that I have attempted to produce decoctions from various sources, and to imitate various strata, or the issues of these strata, and have been fairly successful. This, however, may be considered as raw material, and should not be attempted except by such as have made themselves conversant with the geological distribution of Ferns.

MR. E. MOLYNEUX ON PROPAGATING CHRYSANTHEMUMS.—I am sure all your readers read Mr. Molyneux's excellent contributions with great interest, not so much because he is the champion grower, but because of the great clearness and accuracy with which he conveys his own experience. A vital point in propagating is to give sufficient air to dispel damp, and this more especially with the rare and more delicately grown varieties, that are very

liable to decay before suspected if too moist. He suggests admitting air for an hour in the mornings—of course not referring to frosty mornings—otherwise to keep the house closed for a month or so. The atmosphere in the south of Ireland is generally at "saturation point," during December, January, and February, so that when it is so I find it advisable, as many of my gardening friends do, to tilt the frame behind and ventilate on night and day. I once lost 200 cuttings by keeping them close.—W. J. MURPHY, *Clonmel*.

### NEW VARIETIES OF CELERY.

FROM what has been written lately about the White Plume Celery it does not appear likely to be grown extensively by the majority of people. I have not tried it, but must say I like to see it when grown well on account of its ornamental appearance, but most people require other qualities in Celery besides this.

I have this season tried a variety called Celery Blanc Doré, which was very highly spoken of last spring as not requiring earthing. I should probably have taken no notice of it, as I well knew how the White Plume had failed in the same way, but a gentleman requested me to procure him some seed, and also told my employers what a grand thing it was. I accordingly procured some seed, and in due time some plants were placed out as recommended, without any provision for blanching; but as I had great doubts about the matter, I resolved to try some of it in the ordinary way also in order to thoroughly test it. That planted on the level surface grew rather over 1 foot high, of a pale straw colour, none of it white enough to use, but 15° of frost assisted us, and set all doubts at rest as to what we were to do with it. That planted in the trenches and earthed as usual is short, tough, and stringy, and certainly not fit for use under treatment which has produced Sandringham and other varieties by its side in first-rate condition. New varieties ought to be well tested before they are recommended in the papers to prevent other people being put to trouble and expense for nothing; it should not be any recommendation to a plant to be new unless it supersedes older varieties. I should think Sandringham Dwarf White, under one of its various names, and Major Clarke's Red are grown more than any other varieties by private growers.—W. H. DIVERS, *Ketton Hall*.

### PROFESSIONAL GARDENERS' BENEFIT SOCIETY.

THE annual dinner of the above Society was held at Leeds on Friday, January 8th, about fifty members and visitors from the neighbourhood of Leeds, Sheffield, Wakefield, Huddersfield, and other towns being present. Mr. Joseph Smith presided, the vice-chair being occupied by Mr. Buck. Letters of apology for unavoidable absence from W. L. Jackson, Esq., M.P., and Councillor Loe, were read. After the dinner and the usual loyal toasts the annual report was read by Mr. W. Sunley, the Secretary. It was as follows:—

#### ANNUAL REPORT OF THE PROFESSIONAL GARDENERS' FRIENDLY BENEFIT SOCIETY.

In presenting the nineteenth annual report, your Committee beg to direct attention to the annexed balance sheet, which shows cause for satisfaction.

	£	s.	d.
The Society's income for the past year has been ...	141	10	11
Its expenditure for the same period has been ...	82	1	4½
Which leaves a saving for the past year of ...	59	9	6½
This amount added to the savings of the eighteen previous years of ...	707	7	10
Makes the total amount placed to the Society's credit of ...	766	17	4½

Representing the value to each financial member of £6 19s. 5d.

The total number of honorary members is twenty-three, and the total number of financial members is 110. The mean age of all its members is at the present time about forty-four years.

This fact, along with the knowledge of the amount of funds already accumulated and available by the Society, gives promise of its future prosperity and stability.

Your Committee beg gratefully to acknowledge the very liberal support accorded to the Society by its honorary members, and cordially welcome the seven additional gentlemen who have been enrolled during the past year.

Your Committee will always endeavour to promote the welfare of the Society, and continue to rely on the kindly forbearance and support of the members generally.

Signed on behalf of the Committee,

WILLIAM SUNLEY, *Secretary*.

*Bacchus Hill, Moor-Allerton, Leeds,*  
January 1st, 1886.

Mr. G. Hemming moved the adoption of the report, which was carried with considerable enthusiasm. It will be seen that the Society is in a very satisfactory condition, the amount saved during the past year being considerably above the average, which may be stated roughly to be about £40 per year. The disbursements for sickness amounted to £26 3s. 4d.; for funeral expenses to £37 2s. It may be stated that the Society is not a local one, for its benefits are open to professional gardeners throughout the country. The payments amount to 13s. annually for each member; and an additional 1s. each is levied on the death of a member, and of 6d. for a member's wife. The advantages are that members who are unable to work through sickness are entitled to 10s. per week for twenty-six weeks, and 5s. per week as long as they are ill. At the death of a mem-

ber his widow receives £10: at the death of a wife the member receives £7.

The toast of the evening, "The Professional Gardeners' Friendly Benefit Society," was proposed by Mr. Councillor Milnes of Wakefield, who expressed his approval of the twofold objects of the Society. They were most praiseworthy. A number of men had banded themselves together to help each other and for their mutual improvement. They were laying by money for relief in old age or want. In case of sickness they were not compelled to go to others for assistance, while in the event of their death a sum of money was given for the assistance of their families. He suggested that much might be done to effect mutual improvement in the Society by encouraging its members to read essays at its meetings and by discussions. He stated that the Paxton Society at Wakefield had endeavoured to have essays read at all of its weekly meetings, no less than forty-eight having been read last year. He believed that many members of the Benefit Society could produce instructive essays, and thought it probable that some members of the Wakefield Paxton Society would assist them if desired. Mr. Featherstone, in replying, stated that one of the rules of the Benefit Society was to the effect that any members having interesting specimens of fruits, vegetables, or flowers be invited to exhibit them at the Society's meeting, with a view to discussion thereon. With regard to essays, many had been read, but he reminded those present that as the meetings of the Society only took place monthly, it was impossible to have anything like the number referred to by Mr. Councillor Milnes. Altogether he thought the question of mutual improvement was by no means neglected.

Mr. Franklin referred to the flower show held at Leeds last year, the excellence and success of which were largely due to the efforts of Mr. Featherstone. He trusted other shows would be held this year. The last named gentleman, in responding, stated that he had hoped to organise a Chrysanthemum show last autumn, but the project had to be abandoned through failure to secure a show-room at a suitable time. He should make every effort to institute a Chrysanthemum show in autumn this year. The last summer show had been a very successful one.

Several other toasts were proposed, and a most enjoyable evening was spent by the assembly.

### TEA ROSES UNDER GLASS.

WHEN visiting the hospitable proprietor of the Royal Nurseries, Ascot, recently, I was much struck with the way in which Tea-scented Roses were grown and trained in the extensive houses devoted to their culture for the supply of cut flowers. The main principle seems to be, Avoid training close on to the glass or walls. Thus in a long span-roofed house the Rose trees are planted along the margins of a central bed, and plant stakes are inserted at intervals of about 6 inches all down each side of the bed, and then bent over to meet and be firmly secured together in the middle, forming a complete arcade under which a man can pass if need be. Over this arcade the plants are tied out and trained, making a far more effective display than when trained up under the roof, and also being in a position much better adapted for the operations of pruning, looking for insects, syringing and cutting flowers, while the advantage to the dwarf plants, which may be grown at the sides of the house either in pots or planted in beds, of not having the light from the roof impeded by a leafy screen is obvious. Similarly in the lean-to houses, the trees are planted about 3 feet from the wall. Numerous stakes are inserted by them and sloped to the wall, and upon these the Roses are trained. By this means the walls themselves are left clear, so that they may be readily lime-washed or cleaned without disturbing the plants, which themselves are in a better position to get their wood thoroughly ripened. Two of these long lean-to houses were filled with Madame Falcot looking the picture of health, and a third was entirely occupied by Niphetos, which had been pruned, and was already covered with buds and fresh strong growths, showing how successful was the treatment they received, by the vigorous shoots and early promise of abundant blossom.

There is one long span-roofed house entirely devoted to Maréchal Niel and here the trees planted along the two sides of the house are trained up close under the glass. In this case the ripening and bracing-up of the wood for the task of bearing its annual burden of flowers is effected in another way. The house in question has two strong principals running its entire length upon iron supports, and braced together here and there by iron rods. The roof consists of long rafters of angle-iron running from the apex of the roof to the ground, or rather to piles hardly visible above the surface on either side, so that the cross-section of the house may be represented by a capital letter A. The rafters are sufficiently far apart to admit of the glazing in strong frames of about the width of Cucumber-pit lights, and the glazing between each pair of rafters is in two frames whose junction comes upon the principal, while all are securely fixed in position by means of screws. It will thus be seen that the whole roof (which is practically the house) is arranged in portable and moveable sections, and as soon as the weather becomes warm and settled after the Roses have done flowering the roof is unscrewed and bodily removed for the summer, leaving nothing but the rafters between the trees and the strengthening and ripening influence of the weather. The result is a canopy of sound rods, of a solid appearance too seldom seen in climbing Roses under glass, and surely foreshadowing a golden age in the near future.

The importance of a free circulation of air and light when the plants are making and ripening their wood cannot be over-estimated in the case of Roses, especially under glass where trees are planted for a permanency. Of course pot Roses are easily provided for by standing them out of doors

during the summer, but at Ascot most of the plants used for supplying cut flowers are planted in beds, to their manifest enjoyment. There is another house with *Maréchal Niel* trained under the roof, and beneath its partial shade a forest of *Camellias* simply luxuriates, while houses full of *Gardenias* giving promise of bloom enough apparently to supply all Bond Street, seem to indicate that the estimation in which these favourite flowers are held is not likely to be seriously affected by any ills the plant is heir to. If, however, danger appears in the form of scale or mealy bug, the most effective, as well as the cheapest way of eradicating it, is found to be by means of petroleum and water thoroughly mixed. Among other plants, which were looking as hearty as the *Gardenias* and other hard-wooded plants, were innumerable young *Palms*, including the beautiful *Kentia Balmoreana*, a far more handsome plant for room-decoration than the generally used *Seaforthia elegans*, which was also extensively represented. The finer texture of the leaves of the former makes their deep green colour more noticeable, and the whole plant is more distinguished-looking than is the case with the latter *Palm*.

In a charming houseful of forced spring flowers the pretty *Cytisus Everestianus*, a dwarf fine-leaved form, was especially attractive, and appeared eminently adapted for a room plant, while in another long house (of which there are upwards of thirty all worthily tenanted) the delicious fragrance of masses of *Lily of the Valley* and white *Lilac* *Charles X.*, seemed almost solid enough to be cut with a knife.

There are a good many *Roses* grown out of doors at Ascot, but there is not much temptation at this time of year to investigate them. The nursery outside, however, presents a powerful attraction to lovers of American plants and *Coniferae*, of which there are numerous fine examples of all the leading kinds. Among the more scarce sorts may be mentioned the new French variety of *Cupressus Lawsoniana* *Tom Pouce*, a beautifully outlined and very dense tree, and a very pleasing variation of the well-known *Abies lasiocarpa* *Lowii*, called *Abies concolor*, which has long leaves of a beautiful glaucous blue tint; in fact it might be described as *lasiocarpa* with the colour of *A. nobilis*. The comparatively recent *Abies polita* of Japan, with its stiff noli-me-tangere leaves is also noticeable, while there are exceptionally handsome specimens of the rare *Abies Hookeriana*, a tree whose very distinct appearance, with upright habit and short glaucous leaves, might induce the supposition that this species had at one time been in doubt whether to appear as a *Cedar* or an *Abies*, and had ultimately decided to adopt the characteristics of both.—T. W. G.

#### GROS COLMAN VINE.

I WAS much interested in Mr. Taylor's article on *Gros Colman*, but should like to ask him a few questions. Is he sure it was potash alone that the Vines required? I mean, has a sample of the soil been submitted to an analytical chemist, or has Mr. Taylor's friend sufficient skill to analyse it himself? If so, will he explain the process? What was the liquid manure composed of? In the case of Vines, supposing the insufficient supply to be potash, would the trifling cost be for farmyard manure or "potassium salts"? If the latter, will Mr. Taylor state the best way to apply them and the quantity per square yard? I gather from the remark in the last paragraph that *Gros Colman* needs more potash than other Vines. How did he arrive at this conclusion? Has he tested Vines of different varieties with purely potash manures of different strength to warrant him in making the assertion?

I have just finished a Vine border (an outside one) 3 feet deep, including drainage; and as I was not allowed to pare more turf than would cover the drainage, and cheapness was a *sine qua non*, the soil only consists of two-thirds heavy loam without fibre, and one-third burnt earth with the ashes and charcoal of the wood it was burnt with, and some old mortar. Broken bricks were freely used as it was made up. I intend planting the Vines, and then mulch heavily with farmyard manure, and I think the manure and the wood ashes will give sufficient potash for some time.

As this is my first head place and the first Vine border I have made, I cannot afford to risk my reputation by trying experiments with chemical manures. I have not much doubt but Mr. Taylor's theory is correct, as turf was used, and the grass would perhaps furnish sufficient nitrogen; but it will do no harm if he will answer my questions, and may be useful to other readers of the *Journal* besides.—A. L. G.

MR. TAYLOR, on page 576, opens a subject of importance, and doubtless opinions will differ respecting it. He mentions the opinion expressed by a writer in the *Journal*, which I well remember, that it is beneficial to plant *Gros Colman* at the north or shaded side of the vinery. This advice qualified I think is not far wide of the mark, and whenever opportunity affords I intend to act upon it. I have bestowed a good deal of thought upon the peculiarities of this Vine, and am happy to say not without success.

I hardly know how far I may agree with Mr. Taylor regarding the root treatment, as I am rather liberal with potash, not only for Vines annually, but to outdoor fruits, but also vegetables with good results; yet when I notice *Gros Colman* fail to retain its foliage and assume a transparent reddish colour only in a house where several other varieties, black and white, succeed admirably I feel loth to believe how any special root treatment could very materially stave off the evil. It is difficult to see why *Gros Colman* should need food so entirely different from others. Shade, however, in my opinion is of the utmost importance. For three seasons now I have had the glass over *Gros Colman* painted, or in other words frosted thinly with the best white paint mixed with varnish. It is

very transparent and improved the foliage much, and the bunches were better coloured. I decided therefore to shade still more if bright weather appeared again; and in June last year we fastened over the frosted surfaces cotton well stretched about one-eighth of an inch mesh. This proved very satisfactory, although the foliage became rather tinted; it was of good substance and was retained equally as long as others, especially those leaves which happened to have other large leaves over them. The berries were equal in colour to the best *Alicantes*; in fact, late in August a bunch was given an artist along with some other choice fruits as specimens for painting. Seeing that our Vines have had abundance of potash each season, I can hardly accept it as a remedy, much as I always esteem Mr. Taylor's notes on Vine topics.—LATHYRUS.

WE hear that the HEAVY SNOW has seriously damaged trees in many public and private gardens, branches being torn off by the weight, and numbers of fine specimens are in consequence irrecoverably ruined. The injury has been severely felt at Kew, and *Conifers* have as usual suffered greatly owing to their branches retaining a large quantity of the snow. The depth of snow in the Royal Horticultural Society's Gardens at Chiswick was 7 inches, and the lowest reading of the thermometer last week 14°, or, as it is termed, 18° of frost.

— THE past week has been a somewhat calamitous one to horticulturists, for in a railway collision at Manor Park on the Great Eastern line two well-known persons, Mr. Wallace, jun., of Colchester, and Mr. Horsman of the same town, were both injured, though happily, we believe, not very seriously. On the same day Mr. William Brown of Hendon, a florist who has long held a prominent position amongst the best *Pelargonium* growers round the metropolis, was found drowned in a well in the nursery.

— THE TURNER MEMORIAL COMMITTEE held a meeting at South Kensington, on Tuesday, the 12th inst., but was adjourned owing to the fund at present obtained being insufficient for the intended purpose. A sum of £162 has been subscribed, but it is considered that at least £200 will be required for investment to furnish a permanent fund.

— WE understand that the AMERICAN EXHIBITION which was to be opened in May this year has been postponed until 1887, to avoid clashing with the Indian and Colonial Exhibition at South Kensington.

— AT THE SHOW OF THE DEVON AND EXETER BOTANICAL SOCIETY to be held in Exeter on August 20th, 1886, Messrs. Lucombe, Pince & Co., Exeter, will offer three prizes, value £3 to 15s., for a collection of twelve distinct vegetables. The same firm will hold an exhibition of Hyacinths at their nursery, March 5th, this year, when three prizes, value £2 2s. to 10s. 6d., will be offered for twelve named Hyacinths, distinct varieties.

— MR. F. W. BURBIDGE, Trinity College Botanic Gardens, Dublin, advocates the establishment of an ORCHID SOCIETY on a broad and comprehensive basis, "so that we may really begin the organised study, culture, and exhibition of Orchids in this country for the first time. It is lamentable that the isolated studies of observant individuals should be hidden under a bushel, or often lost altogether for want of a central society or body of experts to which such observations would naturally flow and be preserved." We anticipate that many will be willing to give their support to this excellent proposal, and it will probably lead to some definite results.

— ON Thursday, the 8th inst., Mr. James Udale of Sheffield delivered an interesting LECTURE ON THE CHRYSANTHEMUM at a meeting of the Hull Chrysanthemum Society in the theatre of the Royal Institution, Hull. The history was referred to, but especial attention was given to the culture, which was fully treated. The lecture was followed by a discussion, and votes of thanks to Mr. Udale and the chairman concluded the meeting.

— "W. S." SENDS the note appended relative to using SALT ON ASPARAGUS BEDS:—"The [idea that salt] is beneficial to an *Asparagus* bed does not find favour among all gardeners, some of whom have learned from experience that a heavy application will kill the tender plants.

Many, especially in the United States, are abandoning the practice of applying salt, and claim that neither the yield nor quality of the Asparagus is unfavourably affected."

— A CONSTANT reader writes :—"I should feel greatly indebted to you if some readers of the *Journal of Horticulture* could give me their opinion as to the value of the READING HERO POTATO. We find it an excellent cropper, equal to Magnum Bonum, but very little use for table, as it is a bad colour. Is this usual with the Hero? or is it the fault of the soil, which is a rather heavy loam."

— A CORRESPONDENT, writing from near Henley-on-Thames, observes :—"The HEAVY SNOW that fell on the 6th inst. has caused great injury to trees; a continual crashing of large branches might be heard throughout the day in the parks and woods in the neighbourhood. In places the roads were almost impassable from the falling *débris*, and many branches threatening to come down on the pedestrians."

— A SHORT time ago we announced that MESSRS. WEBB & SONS, Wordsley, Stourbridge, had been honoured with a Special Royal Warrant appointing them seedsmen to Her Majesty the Queen, and we now learn that they have also received a similar Special Appointment to His Royal Highness the Prince of Wales.

— IT is said that there is a CABBAGE FARM of the extent of 100 acres near Chicago. It requires 1,114,000 plants to set it; and counting those used in the resetting, 30,000,000 are required for the whole neighbouring district under cultivation, which comprises 2500 acres.

— "MANAGER" sends the following on EARLY SEED ORDERS—"I write to ask if you will use your powerful influence in the interest of the thousands of seedsmen's assistants who are working very long hours at this season of the year in the execution of seed orders, by advising purchasers not to withhold their orders until the cold weather disappears, but to send them unto their seedsmen as soon as possible whatever the weather may be. It is only those who have had experience of the terrific pressure that is felt in our large retail seed establishments in London and elsewhere at the break up of a frost, such as the present, that can realise the amount of energy necessary to keep up with the work thus accumulated, and early orders are equally desirable in the purchaser's interest, inasmuch that the seeds are at hand for use the moment the weather is favourable for sowing."

— THE annual meeting of the SHEFFIELD FLORAL AND HORTICULTURAL SOCIETY was recently held at the Society's rooms, when the report and balance sheet read and adopted, which showed the Society to be in a very prosperous condition, and to have enrolled a considerable number of new members during the past year. Mr. W. K. Woodcock jun., was unanimously elected as Secretary in the room of Mr. W. K. Woodcock, sen., resigned through pressure of engagements. The remaining officers and Committee were mostly re-elected. A very good list of essays is arranged for the first half of the current year—viz., February 3rd, "The Nomenclature of Plants," Mr. J. Haigh. March 3rd, "The Cultivation of the Gladioli," Mr. T. Marples. April 7th, "The Principles of Gardening," Mr. T. Inman of Leeds. May 5th, "The Lapageria, with other Stove and Greenhouse Climbers," Mr. W. K. Woodcock, sen. June 2nd, "The Destruction of Plant Pests," Mr. J. Walker. A small exhibition of plants and flowers in season will take place at each meeting.

— THE Rev. H. H. D'Ombra's "ROSARIAN'S YEAR BOOK FOR, 1886" is issued, and as usual contains a series of interesting chapters upon Rose subjects. The frontispiece is an excellent portrait of Mr. B. R. Cant, of whose career and successes an account is given by the Editor. A "Symposium of Mildew" includes a chapter by Mr. Worthington G. Smith, illustrated with the figures of the Rose mildew which originally appeared in this Journal; one by Mr. D. T. Fish, a third by Mr. E. R. Whitwell, and a fourth by Mr. E. W. Badger, all of which give many interesting details concerning this troublesome pest. Special reference is accorded to sulphide of potassium as a means of destroying the mildew, favourable evidence from several cultivators being given. The quantity advised to be used is quarter ounce to a gallon of water, syringed on to the plants. An interesting chapter on "Single Roses as Decorative Plants" is contributed by Mr. T. W. Girdlestone. Mr. Alexander Hill Gray descants upon "Roses in the Fortunate Islands." Mr. G. Paul has an article upon climbing and pillar Roses, while Mr. E. Mawley gives us a review of "The Weather," and the Editor has several reviews and notes.

— THE ARTIFICIAL COLOURING OF FRUITS OR VEGETABLES is becoming too common a practice now. A short time since we heard of a number of Potatoes being so treated before being exhibited, and now a correspondent sends this note :—"French gardeners fit their unripe Tomatoes for market by painting or staining them red, giving them the appearance of ripe fruit. The experiment does not always prove a financial success, however, as several such enterprising characters were lately fined 100 francs each for indulging in this method of rendering their products attractive."

— THE report of the SELECT COMMITTEE ON FORESTRY states that it was found impossible to conclude investigations during the past session, and recommends that a Committee on the subject should be appointed in the next session of Parliament. On the general subject of the proposed Forest School, Colonel Pearson, in examination before the Committee, expressed himself in favour of a Chair of Forestry at the Edinburgh University, but he further stated that he had no actual faith in lectures in the school unless illustrated by practical instruction. Regarding the extent or scope of the school, Mr. Thiselton Dyer, in reply to Sir Edmund Lechmere, said he would make the school applicable to India and the Colonies as well as to our own country.

— IN describing the district of Kattiawar, India, a correspondent thus refers to the ASOKA or "SORROWLESS TREE" (*JONESIA ASOCA*), which grows freely there. "Its spear-shaped wavy leaves are not now diversified by the bright blossoms of scarlet and gold which Wasanta time will bring, but there is no tree more celebrated in Indian poetry. It was to the Asoka that Damayanti addressed her pretty appeal, in the 'Mahābhārata,' when she adjured the 'Heart's Ease' to tell her where Nala had gone. The soil hereabouts is full of nitrous salts, which dry in a white crust wherever water has been. Yet it is evidently very fertile, and full of wells, built with the sloping platform, where white bullocks draw the big skins of water up, and then go backwards to plunge them in again to the monotonous song of the byl-wallah. But Kattiawar wants trees. Trees will save India, and are saving her, from the fate of Central Asia, desiccated by nakedness. The Forest Conservancy, promoted by the British Rāj, is one of its greatest benefits to the peninsula. India would have been a 'howling wilderness' if the sway of the Mogul or the Mafratta had lasted. It is her trees which hold the precious water in the earth and give shade, moisture, life. The Peepul, the Asoka, and the Aswattha have never been half enough worshipped. Every forest officer is the priest of a true religion."

#### CANKER AND INSECTS—OUR PRESENT STANDPOINT.

THIS is a matter which has not unreasonably occupied some space in this Journal, and may be expected to claim more before sundry queries that have been suggested can be satisfactorily solved. I have been lately engaged in some investigations concerning canker, and though I will not venture to speak with too much positiveness, I am still of the belief that the insects are to be exonerated. Firstly, it should, however, be stated that so far as I have inquired amongst fruit-growers, the majority of them do attribute canker to an insect rather than a vegetable cause. This notion on their part must be taken for what it is worth—that is to say, on matters of culture they may reasonably be expected to know what appertains to their calling, but on a question of insect economy they have seldom the means of forming a judgment, especially where it is one of some difficulty. Entomologists generally have sadly neglected the study of these minute species; those few who are competent to form an opinion are here almost to a man prepared to vindicate the insects. One observer asks whether there may be running together two maladies, one popularly designated canker and of vegetable origin, the other due to the attacks of mites, but in its symptoms resembling the former. This is not a theory that has much plausibility, nor is it, I should say, likely to meet with support, though gardeners differ considerably in their descriptions of canker, and it may have been confused with what an editorial note calls "ulceration." What I understand by this term is an appearance on the branches, or perhaps on the stem of young trees, which is not attributable to the work of mites or other tiny insects, but is caused by the occasional gnawing of caterpillars whose wonted food is the leaves. But possibly ulceration is differently understood by some people or explained differently.

Now, there are certain conditions of tree life under which we may expect to discover canker; this is allowed by those even who connect insects with it. Fruit trees in crowded neglected orchards are liable to it, also trees growing in heavy clay soils or in an impoverished soil, specially, that is, in soil lacking phosphates and nitrogenous compounds. Old and much cultivated, possibly worn out varieties, are thought to be its particular subjects. My friendly opponent, Mr. Hiam, lays much stress upon the circumstance that branches or twigs with signs of canker occurred upon trees which he believed were radically healthy, but how can this be proved? To take an instance for comparison from our own race: it is

familiar to us that sometimes from the effects of a trifling ailment a man suddenly dies, and the explanation often is that under previous apparent health there lay an actual unsoundness. This may be the case in the plant world, and a specimen be secretly diseased which we think is flourishing. Again, he argues that another proof the mischief is caused by insects is the success he has found in local applications of a suitable kind, but the process employed by its cleansing effect might be equally good in curing a vegetable disease. I will concede, and in so doing perhaps may put a weapon into the hands of the other side, that there are mites which to the best of our knowledge do attack plants in health, though unhealthy ones may run greater peril of injury. As examples I may cite the too common red spider and the whole group of gall mites that swell or disfigure buds, leaves, and twigs. But it has long been recognised as a truth by entomologists, that in the economy of Nature hosts of other mites are constantly busy in the work of disintegrating what has begun to decay. Some come, therefore, to the moist patches to be seen in cankered Apples and Pears, and feast on the juices that exude, or, possibly, to feed on a microscopic fungoid growth that is developed on branches thus diseased. One naturalist tells me that he has examined cankered samples, but found no mites at all; still I would not argue from this, because they might have been washed off, or have migrated, or been devoured by parasitic enemies. Then there is this noteworthy and positive fact to be considered, that little parties of mites may be found upon the bark of fruit trees that are neither cankered nor diseased in any way. One of these is the tolerably abundant beetle mite called *Damæus geniculatus*, which occurs in parties made up of specimens of all ages, and which has been thought by the Germans beneficial to the trees rather than the reverse. This, I suspect, is not the species which Mr. Hiam has brought to light and elsewhere noticed, but probably Boisduval's *Acarus Pyri*, which would occur on both Pear and Apple. It appears to have been hitherto overlooked by entomologists here, and I hope shortly to be able to get its name determined by a competent authority in this division.—ENTOMOLOGIST.

#### NOTES ON CHRYSANTHEMUMS.

I do not agree with Mr. Iggulden that *Anemone Japanese Chrysanthemums* are eligible to be staged with the ordinary Japanese forms, as this would be setting a precedent which, in my opinion, is wrong. The name of *Anemone Japanese* was given to these newer forms as indicative of their distinctness, and I am not aware that any Japanese variety is in any way sufficiently allied to the *Anemone Japanese* in construction as to be admissible in a stand of *Anemone* flowers. If *Anemone Japanese* are to be allowed in Japanese stands, why cannot the ordinary Japanese flowers be staged with *Anemone Japanese*? Fancy an exhibitor staging a bloom of *Madame C. Audiguier*, for instance, in conjunction with *Fabian de Mediana*! Mr. Iggulden would be compelled to pass this in the same way as he considers justifiable in the other case, and a pretty state of things we should get into soon. I do not think our regular *Chrysanthemum* judges are likely to allow this. I think judges are more to blame than exhibitors in some cases for allowing such mistakes to pass. Intending exhibitors see that Mr. So-and-so was awarded first prize, having such and such varieties in his stand, and when hard pressed to find the necessary number of blooms of the proper kinds fall back on these convenient auxiliaries. I know that no rule has been laid down for strict guidance, nor can I see how rules can be made to meet every extreme case that may crop up; but I do not mean the case in question to be one of these extremes. It was simple enough to my mind.

*Chrysanthemum* societies with any pretensions to greatness should make separate classes for the *Anemone* and *Anemone Japanese* type, because the latter are so much more attractive that the former is almost sure to get elbowed out of the exhibition room; at any rate, they are too stiff in appearance alongside of their more gracefully disposed brethren, and public taste is more in favour of freedom or even fantastical shapes than strictly formal outlines. The cause of so few additions to the incurved section is through seed being produced so sparingly I presume, and the present general system of growing *Chrysanthemums* is certainly not adapted to the production of sports, therefore I am not at all surprised that so few new ones appear. Some persons speak disparagingly of sports. I have yet to learn why they are not so good as seedlings. Take Lord Alcester, for instance, which was a sport, I believe, from *Golden Empress*, and has worked its way quite to the front. It is a grand variety, producing more first-class flowers on a given number of plants than any other variety in existence when grown under favourable circumstances, which cannot have been the case in Mr. Iggulden's hands, or he would not be compelled to dub this variety "tricky," and his blooms must have been in a bad state when "all the dressing in the world" failed to restore their lost form. I am afraid Mr. Iggulden's experience of Lord Alcester during the last season is not encouraging to persons who contemplate growing his lordship during the coming season. I advise them not to hesitate, as perhaps the "trickiness" was in the hands of the grower, and not in the variety; and also that "all the dressing in the world" was not applied to the flowers in question.

Double centres in flowers are in my opinion the result of a check some time during the early stages of the growth of the buds, probably by lack of water in hot weather. I am strengthened in this idea by the fact that more complaints are heard of double centres after hot dry seasons than after those moderately dry. Ripe wood must be had if high-class flowers are desired, but it must not be prematurely effected; regularity must be the order of the day if success is to be obtained.

I am much surprised to hear of an incurved sport from Mrs. Forsyth,

which is a reflexed flower. Is the parent rightly named? *Golden Queen* of England gave some trouble last season through its persistency to reflex its petals instead of incurve them. This, again, was not the fault of the variety, but was caused by the blooms being grown at the wrong time.

Mabel Ward and *Eve* are fast becoming obsolete; the petals are much too narrow, and they are so uncertain in producing blooms large enough for exhibition purposes. *Jardin des Plantes*, the finest of all the yellows, is somewhat spoilt by the habit it sometimes has in giving blooms with split centres, particularly when the flowers are grown large in size. Mr. Bunn is a capital flower, something like the former in colour, but its great objection as a decorative variety is its tendency to droop when in bloom, the peduncles being so thin.

Princess of Wales and Mrs. Heales have as usual caused some controversy as to their distinctiveness. I consider exhibitors have themselves to blame often in this matter. When once known these varieties are easily recognisable. It is quite possible to cut flowers closely resembling both varieties from one plant of Princess of Wales. This is caused by the buds being "taken" at different stages. Those resembling Mrs. Heales are "taken" too soon, thus causing the paler colour. They are exactly alike in growth, colour of foliage, and shape of the buds. The colour of Princess of Wales is white suffused with a very pale shade of pink, and each petal is striped with the same colour; this is when produced in its proper and natural character. Flowers not having these characteristics when staged lose a point when in competition, and when judged by men who know the character and quality of the variety. Mrs. Heales is generally a little smaller in size than the Princess; its colour is white, suffused with pale cream, no trace of pink being discernible except when the bottom petals get tinged with age.

I do not yet know what class *Salteri* belongs to; to me it does not appear to belong to any, so peculiar is it in shape. I imagine it will have a very short existence amongst the general growers. Japanese varieties are getting too numerous; there are many worthless forms in existence. I think catalogue descriptions of new varieties are much too elaborate; if more simple, I am sure it would be of greater service in selecting. It is impossible for gardeners to grow all the new kinds as they are introduced. Fascinated by the descriptions in catalogues, growers burden themselves with far too many varieties, which often ends in disappointment when the time for blooming arrives.

Pompons and *Anemone Pompons* ought to be disbudded and staged with about 6 inches of stem with the foliage attached. These tied in bunches of three or five are very attractive. When they are disbudded the true character of each variety is brought out, and the work of awarding the prizes is more simplified than when staged in bunches of perhaps ten or a dozen blooms on each shoot. I strongly recommend the disbudding system for exhibition, but for home decoration I prefer some grown as bush plants with a profusion of flowers.—E. MOLYNEUX.

#### POTATO EXHIBITIONS—COLOURING POTATOES.

SOME of the Potato growers who visited the Birmingham Cattle Show at Bingley Hall in December have a strong conviction that some of the samples of red and purple Potatoes exhibited there were artificially coloured, and that this led to their taking the leading prices. I did not see the exhibits, but a gentleman connected with a leading seed firm in Birmingham told me that he felt confident that some of the sorts had been dyed or painted to lighten their colour, and recommended me to write to a well-known seed firm in the midlands for further information.

I did so—I enclose you their letter in reply—and their letter I take the following extract—"As regards the painted Potatoes at Birmingham, there were the usual sorts, such as *Reading Russet*, *Prizetaker*, *Mr. Bresee*, &c., which were very coloury even when the dust settled upon them, the colour almost equal to Venetian red, but of a more carmine rose tint."

I mention the circumstance as I think it is so desirable that a stringent rule should exist in every schedule that any attempt whatever to lighten the natural colour of the Potato should lead to disqualification. If it is a fact, and my informant is emphatic in his opinion, that the tubers in question were artificially coloured, what were the judges about not to have disqualified them?—SOLANUM.

#### ROSE PRIDE OF REIGATE.

TWO or three years ago Mr. James Brown, gardener to A. J. Waterlow, Esq., Great Doods, Reigate, exhibited a bloom of a sport from *Comtesse d'Oxford* at one of the National Society's Kensington shows, and it at once attracted much attention, though some doubt was expressed at the time as to whether it would prove constant. Since then it has been shown on several occasions, and the characters were each time found to be so true that on July 23rd of the present year the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for it to Messrs. Paul & Son, Cheshunt, who had purchased the stock. Like its parent, it is of good globular form and a pleasing light crimson colour, but this is strikingly diversified by regular pure white stripes through the petals, giving the bloom a remarkable and beautiful appearance. In a stand of Hybrid Perpetuals it is most conspicuous, and as the sport shares the characters of the parent, which is described by the National Rose Society

as "a reliable Rose," there is every reason to expect that it will become very popular.

The bloom represented in our woodcut (fig. 6) was forwarded to us by Messrs. Paul & Son, and faithfully represents the form and markings.

#### A GLIMPSE OF AFRICAN VEGETATION.

THE following extracts from a most interesting book called "The Kilima-Njaro Expedition," which is just published, and which should be read by all who can obtain it, may interest some of your readers. I may first say that "Kilima-Njaro" is a huge mountain mass in Eastern Africa, consisting of two giant peaks and many smaller ones. It is situated below the third parallel south of the equator, and is distant about 175 miles in a straight line from the coast. The highest peak is called Kibo, and is 18,880 feet above the sea. The lesser peak is K'mawenzi, and

Heaths begin to appear, and the Orchilla Lichen covers nearly all the forest with a grey-green veil. Between 8000 and 9000 feet the giant Senecios are met with, and continue upwards till near the borders of the snow. Gorgeous crimson Gladioli, pale pink and mauve, and cerulean blue lilies grow to great altitudes; indeed, some of the flowers of the grassy uplands between 10,000 and 14,000 feet, are particularly brilliant in colour. There are vivid blue Cynoglossums, the blush-pink Everlastings, the yellow Euryops, the strange straw-coloured Proteas, with red bracts and red leaf-shoots, the small coloured Lobelias (*L. Deckeni*), and many others which it would be tedious to catalogue."

After an altitude of 14,000 feet "one is left with a few Artemisias (Southernwood), Heaths, and Everlasting Flowers, until at length they too disappear, and there remain little red and greenish Lichens, expanses of yellow sand, lead-coloured rocks, black boulders, and snow."

"To the ordinary mind, even of an unreflecting traveller, there is something very wonderful and imposing in the aspect presented by such a

Fig. 6.—PRIDE OF REIGATE.

attains an altitude of 16,250 feet. Both ascend above the snow line, and are craters of extinct volcanoes.

Much more interesting matter concerning these grand mountain peaks is given in the introduction to the book, but space forbids quotation here. I would, however, hope that room may be found for the following.

"The Flora of Kilima-Njaro is naturally interesting, as may be imagined from the extraordinary range of climate between the eternal snows of the summits and the hot tropical plains at the base."

"The lower slopes of Kilima-Njaro are exquisitely green, and scarcely a patch of earth remains uncovered, but the general aspect of vegetation recalls our English Devonshire and not the tropics. Bushy trees crown the hilltops, or choke the narrow valleys. The grassy downs are covered with patches of Bracken and scented with low-growing Mint.

"The native lanes are bordered with Brambles and magnificent Ferns, some of which belong to common European genera. There are, besides, other plants more properly African which do not mind the colder climate of the uplands, such as *Dracenas*, *Aloes*, *Strychnias*, *Balsams* and ground Orchids. In some of the stream valleys the *Musa Ensete*, a wild Banana, grows luxuriantly up to about 6000 feet and down to 3000 feet, or a little lower if there is water."

"At a height of 7000 or 8000 feet Tree Ferns may be met with belonging to the species *Lonchitis pubescens*. Then above that the arborescent

region as Kilima-Njaro. The summits clothed with virgin snow, the upper regions bearing the humble plants of temperate climes, the Heaths, the Hound's-tongues, the Forget-me-nots, the Buttercups, Clematises, Anemones, Violets, and Geraniums, the Bracken, Polypodies, and Male Fern that are always associated with the Flora of our chilly lands; and then, descending through rich forests of Tree Ferns, *Dracenas*, and Moss-bung Mimosas to the vegetable wealth of the equatorial zone, to the wild Bananas, the Palms, the Orchids, the India-rubber Creepers, the Aloes, and the Baobabs that are among the better known of the myriad forms of vegetation clothing the lower spurs and ramparts of Kilima-Njaro."

The book, which is a handsome one, extending to over 550 pages, is copiously illustrated from sketches by the author, and teems with interesting descriptions of plant life, scenery, insect, animal, and human habits and customs. The natives, though living in such beautiful surroundings, seem to have their full share of human weaknesses, war being fiercely carried on by one tribe against another. Our author nearly came to grief among their quarrels. But it is to Mr. Johnston's descriptions of plant life that readers of the Journal will most naturally turn, and I think no one will say after reading them that Kilima-Njaro is likely soon to be excelled in the way of a mountain wonderful, beautiful, and interesting from base to summit.—J. THOMSON.

NOTE.—The book is published by Kegan Paul, Trench & Co., Patern-

noster Row, London. Mr. Johnston started from London on his travels in the beginning of March, 1884, spent a month at Zanzibar, and then proceeded to Kilima-Njaro. Mr. Johnston returned to London on the 31st Dec., 1884, as he says, "Not much more than six weeks after I last saw the snow peaks of Kilima-Njaro from the reedy shores of Lake Jipe;" and this, with some delays by the way; so much for transit in this age of steam.—J. T.

[We have read attentively the book referred to. The author is an accomplished scholar, experienced traveller, and graphic writer. His work teems with interest, and the information imparted cannot fail to be of great value in the colonisation of what is aptly described as the "new world of the nineteenth century." It should be added that the mountain of Kilima-Njaro is so large that more than one African kingdom is established on its fertile and beautiful slopes, and the thoughtfulness and enterprise of the natives are displayed in the storage and ready method of conducting water to cultivated plateaus—a hopeful sign of coming civilisation.]

## COMMITTEES OF THE ROYAL HORTICULTURAL SOCIETY FOR 1886.

THE following are the names of the members of the three Committees of the above Society nominated for the ensuing year.

### SCIENTIFIC COMMITTEE, 1886.

#### CHAIRMAN.

Sir Joseph Dalton Hooker, K.C.S.I., M.D., C.B., F.R.S., V.P.L.S., Royal Gardens, Kew.

#### VICE-CHAIRMEN.

Godman, F. Du Cane, F.R.S., 10, Chandos Street, Cavendish Square.

Grote, Arthur, F.L.S., 42, Ovington Square, S.W.

Masters, Maxwell T., M.D., F.R.S., Mount Avenue, Ealing, W.

#### SECRETARY.

Rev. G. Henslow, F.L.S., F.G.S., Drayton House, Ealing.

Baker, J. G., Royal Herbarium, Kew.

Bennett, Alfred W., M.A., B.Sc., F.L.S., 6, Park Village East, W.

Berkeley, Rev. M. J., F.R.S., Sibbertoft, Market Harborough.

Boulger, G. S., 9, Norfolk Terrace, Bayswater, W.

Brockbank, Wm., F.L.S., Brockhurst, Didsbury.

Burbidge, F. W., F.L.S., Trinity College Gardens, Dublin.

Church, A. H., F.C.S., Royston House, Kew.

Dod, Rev. C. Wolley, Edge Hall, Malpas, Cheshire.

Elwes, H. J., Preston House, Cirencester.

Glaisher, James, Dartmouth Place, Blackheath.

Honston, D., F.L.S., 179, Mayall Road, Herne Hill, S.E.

Lee, Wm., Downside, Leatherhead.

Lowe, Dr. Wm. Hy., Woodcote, Inner Park Road, Wimbledon.

Llewelyn, J. T. D., F.L.S., Penllergare, Swansea.

Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.

McLachlan, R., F.R.S., Lime Grove, Lewisham.

Michael, Albert D., Cadogan Mansions, Sloane Square, S.W.

Murray, G., Natural History Museum, South Kensington, S.W.

O'Brien, James, Harrow-on-the-Hill.

Pascoe, F. P., F.L.S., 1, Burlington Road, Westbourne Park, W.

Plowright, C., 7, King Street, King's Lynn.

Ridley, Henry N., B.A., Natural History Museum, South Kensington, W.

Smee, A. H., The Grange, Wallington, Surrey.

Smith, Worthington G., F.L.S., 33, Kyverdale Road, Stoke Newington, N.

Wilson, A. Stephen, North Kilmundy, Summerhill, Aberdeen.

### FRUIT COMMITTEE.

#### CHAIRMAN.

Hogg, Robert, LL.D., F.L.S., 39, St. George's Road, S.W.

#### VICE-CHAIRMEN.

Blackmore, R. D., Teddington.

Lane, John E., Berkhamstead.

Rivers, T. F., Sawbridgeworth.

#### SECRETARY.

Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Bunyard, George, The Old Nurseries, Maidstone.

Burnett, J., The Gardens, Deepdene, Dorking.

Crowley, Philip, Waddon House, Croydon.

Denning, W., The Gardens, Lonsborough Lodge, Norbiton, Surrey.

Ellam, Joseph, The Gardens, Cliveden, Maidenhead.

Ford, Sidney, The Gardens, Leonardslee, Horsham.

Godman, F. Du Cane, F.R.S., 10, Chandos Street, Cavendish Square, W.

Goldsmith, G., The Gardens, Floore House, Weedon.

Haywood, T. B., Woodhatch Lodge, Reigate.

Mason, Major F., The Firs, Warwick.

Miller, W., The Gardens, Coombe Abbey, Coventry.

Miles, George T., The Gardens, Wycombe Abbey, High Wycombe.

Norman, G., Hatfield House, Hatfield.

Paul, William, Waltham Cross, N.

Roberts, J., The Gardens, Gunnersbury Park, Acton.

Ross, Chas., The Gardens, Welford Park, Newbury.

Rutland, F., The Gardens, Goodwood, Chichester.

Saltmarsh, T. J., The Nurseries, Chelmsford.

Silverlock, Charles, 412, Strand, W.C.

Smith, James, The Gardens, Meutmore, Leighton Buzzard.

Sutton, Arthur W., Reading.

Veitch, H. J., F.L.S., Royal Exotic Nursery, Chelsea, W.

Warren, W., Worton Gardens, Isleworth.

Weir, Harrison, Henwick Lodge, Lansdown Road, Tynbridge Wells.

Willard, Jesse, Holly Lodge Gardens, Highgate, N.

Woodbridge, John, The Gardens, Syon House, Brentford.

### FLORAL COMMITTEE.

#### CHAIRMAN.

Geo. F. Wilson, F.R.S., Heatherbank, Weybridge Heath.

#### VICE-CHAIRMEN.

O'Brien, James, West Street, Harrow-on-the-Hill.

Hibberd, J. Shirley, 1, Priory Road, The Green, Kew.

Williams, B. S., Victoria Nursery, Upper Holloway.

#### SECRETARY.

Archibald F. Barron, Royal Horticultural Society, Chiswick, W.

Baines, Thomas, Fern Cottage, Palmers Green, N.

Ballantine, H., The Dell Gardens, Egham.

Bealby, William, The Laurels, Roehampton Park, Putney Heath, S.W.

Bennett, H., Shepperton, Walton-on-Thames.

Cannell, Henry, Swanley.

Dean, R., Ranelagh Road, Ealing.

Dominy, John, 11, Tadema Road, Chelsea, S.W.

Douglas, J., The Gardens, Great Gearies, Ilford, E.

Dunfield, G., The Gardens, Bamford Lodge, Winchmore Hill, W.

Herbst, H., Richmond Road, Kew, Surrey.

Hill, E., The Gardens, Tring Park, Tring.

Holmes, W., Frampton Park Nurseries, Hackney.

Hudson, James, The Gardens, Gunnersbury House, Acton.

Kellock, W. B., F.L.S., Stamford Hill, N.

Laing, John, Stanstead Park, Forest Hill, S.W.

Lendy, Major, Sanbury-on-Thames.

Low, Hugh, The Nurseries, Clapton, E.

Low, Dr. W. H., Woodcote, Lower Park Road, Wimbledon.

Masters, Maxwell T., F.R.S., Mount Avenue, Ealing.

Noble, C., Sunningdale Nursery, Bagshot.

Paul, George, "Old" Nurseries, Chess-hunt, N.

Perry, Amos Isaac, Stamford Road, Page Green, Tottenham.

Pollett, H. M., Feriside, Bickley, Kent.

Turner, Harry, Royal Nursery, Slough.

Walker, J., Whitton, Middlesex.

Wilks, Rev. W., Shirley Vicarage, Croydon.

## KEW GARDENS IN WINTER.

A REFERENCE to Kew Gardens and their work, says the *Daily News*, can never be altogether unseasonable, simply because the sphere of that work is the British Empire. Whatever may be the season or the weather on the banks of the Thames, we may be quite sure that somewhere about the globe the prime of the summer sunshine is fostering into perfection groves and plantations, woods and shrubberies, that have originally emanated from this great national nursery, to the directorate of which Mr. Thibetson Dyer has just been advanced. This gentleman, who has been connected with Kew for the past thirteen years, succeeds Sir Joseph Hooker, who retires from this onerous and responsible position in order that he may devote himself to the scientific arrangement of the flora of India at the splendid herbarium which forms part of the establishment here.

Perhaps when leisured Londoners have advanced a little further in their artistic education they may find a good deal to attract them down to Kew Gardens, even in the winter time, and even apart from the wonderful display of Ferns and foliage and flowers always to be enjoyed under the ten or fifteen acres of glass comprised within the gardens. In the depth of winter the grounds are always more or less beautiful—sometimes exquisitely beautiful—with their majestic timber, their masses of shrubs and verdant lawns, here and there touches of brilliant colour or long vistas of grey and blue mist. Nothing of the kind could be more enchanting—except perhaps the same thing under bright sunshine—than the scene down here just after the recent heavy snowfall. Of course wooded country is always charming after a fall of snow, but on few spots of the same extent anywhere on the face of the earth does the snow drape so wonderful a variety of plant life as here in Kew Gardens. The Cedars and Cypressess, Deodars, Pines, and Firs were magnificent objects, and here and there were clustered among the delicate tracery of the deciduous trees in the most bewitching combinations. A heavy fall of snow always does much damage here; it crushes down shrubs and wrenches off great limbs of trees; but even the wreckage is muffled up into forms of fantastic beauty, and while the snow remains hardly detracts from the quaint unfamiliar charms of the scene.

Few people, comparatively speaking, find their way down here in the winter, and perhaps fewer still have any idea of the nature of the work carried on here all the year round, at a cost of £20,000 a year, and with a staff numbering altogether some 170 or 180 people of one grade or another. There are a great many botanical gardens in different parts of the world, and parks and pleasure grounds are of course still more numerous; but Kew is quite unique, simply because the British Empire is unique. For the fifty or sixty governments under the British Crown this establishment is the great botanical clearing-house, and in the depth of winter just as in the height of summer they are taking in here seeds and plants from all corners of the earth, and either propagating them themselves or transmitting them for the enrichment of some distant dependency where they have hitherto been unknown. Exchanges are also made with foreign countries, and however stormy the political horizon may be there is a constant influx of correspondence into the pigeon-holes of the Director's office here, in all the principal languages of Europe, all of it profoundly pacific in its tone, and purely scientific in its interest. "Why can't they settle these squabbles on a botanic basis?" wrote the philosophers of St. Petersburg the other day when England and Russia seemed to be drifting into war over the Afghan difficulty. However high the tide of excitement may rise among nations and their rulers, Kew and its correspondents go on their beneficent way as placidly as though all the world had actually beaten their swords into ploughshares and their spears into pruning-hooks.

There is, perhaps, no department of the public service more thoroughly cosmopolitan than this office of the Director of Kew Gardens. It is a centre of collection and distribution for the whole earth, and a focus of light converged from all quarters of the world and reflected upon whomsoever may need it for scientific or commercial purposes. A broker, for instance, in the City gets some vegetable product transmitted to him, say, from some part of India. This correspondent out yonder wants to know if he can find a sale for it. The broker, however, is in profound ignorance as to the nature of the plant or the uses to which it may be put. He will probably find that there is more information available at Kew than he would get at if he were to go out to India and spend six months in investigating the subject. There are probably about 14,000 species of plants in India, and in the herbarium at Kew Gardens they have actual specimens of somewhere about 11,000 of them. The chances are, therefore, that this vegetable product, whatever it may be, is among the treasures of the herbarium, and that ample information may be obtained about it. This herbarium is a department of Kew not accessible to the ordinary visitor to the gardens. It is located in the old-fashioned red brick house on Kew Green which was formerly occupied by the King of Hanover. A fine lofty and spacious hall with two galleries all round it was added to the back of this house about ten years ago, and here is gathered a collection which missionaries, travellers, naturalists sent out with military expeditions, and resident botanists all over the world are continually enriching, and which is rapidly becoming completely representative of the flora of all the more familiar regions of the earth, as well as of a great many of the more remote. The specimens here are carefully dried and neatly arranged in sheets of cartridge paper and stored away in cases on shelves, after the manner of a library. This is not open to the public; but in the way just explained the public have the benefit of this collection, and anybody who can show a reasonable ground for desiring access to it is readily admitted. It is not a school for students of elementary botany, but anyone who can make it helpful in their study of the science in its higher branches is freely welcome. Last year several Continental botanists of distinction had the privilege of studying here and the use of the considerable library attached to the herbarium. It is in one of the rooms of this establishment that Sir Joseph Hooker is now about to settle down to the completion of his task with the Indian flora after some twenty years of service as Director of the Gardens over which his father, Sir William Hooker, presided for just upon a quarter of a century. Sir William's predecessor, by the way, retired after fifty years' service, so that for nearly a century past this office of Director of Kew Gardens has been held by only three men. This department of practical science certainly would seem to be very conducive to longevity.

No other nation has such an institution as Kew, and no other nation has so much need of it. Its influence on our Colonial Empire has been simply incalculable, and the annual outlay upon it—even if the public derived no benefit from the institution as a pleasure ground and a place of education—would certainly be a mere flea-bite if we could only show in comparison with it the commercial advantages it has conferred. The expense, by the way, would be enormously greater but for the system of exchange that has been so widely developed. Almost everything in the way of seeds and plants for cultivation which Kew requires is obtainable by this system, or by the gifts of Englishmen who have settled abroad and who feel a kindly interest in this great establishment which so pleasantly links together our colonial empire. A resident in Burmah, for instance, lately sent home an offer of a fine collection of Orchids, which were gladly accepted. East India Orchids are easily obtainable; but a few South Americans present an exception to the general rule. We have comparatively little intercourse with the South American continent, and Orchids from that quarter are collected mainly by the travellers of nurserymen, from whom of course they have to be bought. But this rarely happens. Kew has something which the West Indies want, and in exchange for which the West Indies will send something that they have and which Kew wants. Or exchanges are effected between the gardens here and other botanic gardens throughout the country, or with nurserymen or private cultivators and amateurs. Growers all over the world have thus an easy medium for the supply of their wants, and, whether their object is to introduce altogether new things or to improve their stock by the substitution of newer kinds, they will find what they want by communicating with Kew. Thus some time ago Jamaica growers of Pine Apples wanted a new stock. The Director of Kew was able to obtain suckers of the very best kinds in cultivation from the gardens of the Queen, the Duke of Devonshire, Lord Rosebery, and one or two other distinguished growers in England. In other ways also this establishment exerts a great influence on commercial affairs. Many of our colonists are apt to get very much behind their times and to fall very much into the dark as to what is going on in the great world around them. Thus, it recently came to the knowledge of the Government that Oranges were being shipped from Sicily for the New York market, while Jamaica—splendidly adapted for Orange-growing—was rapidly being ruined in the attempt to bring their cane sugar into the market in competition with the bounty-supported Beet-growers of the Continent. Oranges certainly ought to be taken into New York from Jamaica more cheaply than they can be taken from Sicily, and the attention of the Director of Public Gardens and Plantations of Jamaica has been called to this opening for enterprise. That is an illustration of what is continually being done by this great central dépôt. The study of botany is promoted all over the world, the productiveness of our colonies is immensely augmented, every land under the sun is being beautified by the introduction of exotic plants, and here close to the greatest centre of our population we have a garden of the most enchanting beauty, and a collection of foreign plants which are the envy of scientific foreigners all over the world. Some day, perhaps, we may have added to Kew Gardens the forty acres of waste land at the present time given up entirely to solitude and hosts of rabbits, just at that corner of the grounds facing Sion House. At present it is of no use to anybody; there is nothing in it but thickets and trees, and the Queen's cottage, into which no one ever goes, and the whole domain of forty acres is religiously wired round sufficiently to keep out the public, but not sufficiently to keep in the rabbits.

## ROYAL HORTICULTURAL SOCIETY.

JANUARY 12TH.

The severe weather deterred many exhibitors from contributing to this meeting, and in consequence few plants were shown. It was indeed the smallest, and but for the Orchids would have been the least important gathering that has been held at Kensington for some time.

**FRUIT COMMITTEE.**—Present: Dr. Hogg, in the chair, and Messrs. Harry J. Veitch, G. Norman, W. Warren, John Woodbridge, Charles Ross, G. T. Miles, Wm. Denning, J. T. Saltmarsh, Arthur W. Sutton, Sidney Ford, Wm. Paul, R. D. Blackmore, Chas. Silverlock, Phillip Crowley, and John Burnett. Mr. Allen, The Gardens, Gunton Hall, sent a seedling Apple called Lady Sniffeld, which was considered too small for a kitchen Apple, and not good enough in flavour for dessert. Mr. Mitchell, The Gardens, Aberaman, Aberdare, sent a fine specimen of Smooth Cayenne Pine, to which a vote of thanks was awarded. Mr. John Walker, Thame, Oxon, sent some specimens of Walker's Exhibition Onion, a good strain of the Reading or Nuneham Park variety, to which a letter of thanks was awarded. A very interesting collection of stewing Pears was exhibited from the garden of the Society at Chiswick, and the Committee made a selection of varieties which they recommended should be stewed and exhibited at the next meeting.

**FLORAL COMMITTEE.**—Present: G. F. Wilson, Esq., in the chair, and Messrs. J. Douglas, James Walker, H. Bennett, W. Bealby, H. Herbst, Thos. Baines, G. Duffield, W. Holmes, R. Dean, H. Ballantine, A. H. Lendy, J. Dominy, H. Cannell, James O'Brien, E. Hill, G. Paul, and Harry Turner.

**ORCHIDS.**—*Pruning Lælia*.—The meeting owed its principal interest to the Orchids shown by various growers, and one specimen which received the close attention of the Committee was a handsome example of *Lælia anceps* from Mr. Blandford, gardener to Mrs. Haselfoot, Moor Hill, Westend, Southampton, for which a cultural commendation was awarded. The plant had over forty pseudo-bulbs with strong healthy leaves of a rich green colour, indicating the most vigorous health, and it bore ten spikes 3 to 4 feet high, with four or five flowers each. It was shown as an example of the pruning system, and in a note accompanying the specimen it was stated that the plant had been subjected to pruning since 1873, the old pseudo-bulbs being removed when the leaves had faded. It was also said that the plant had been in the same pot for nearly five years. There was some difference of opinion concerning this pruning, as it is termed, but the general view was that the plant had been well grown and had not benefited by the removal of pseudo-bulbs in any way except in rendering it neater in appearance.

*Lælia anceps* varieties.—From Baron Schröder's garden, The Dell, Egham, Mr. Ballantine brought a beautiful collection of *Lælia anceps* flowers, representing all the best varieties in cultivation and showing the

beauty of this useful winter-flowering Orchid to the best advantage. *L. anceps alba* has pure white flowers except a yellow centre in the lip. The sepals and petals are broad, and the flower substantial in general appearance. *L. anceps Barkeriana* is a noted rare variety, remarkable for the grand intensely rich crimson lip and rosy purple sepals and petals. *L. anceps Dawsoni* is a superb form, one of the most valuable and beautiful of all. It was named in honour of the late T. Dawson, Esq., of Meadow Bank, in whose collection it first flowered in 1867. It also flowered a few months later at Gravelly Hall, Birmingham, and this plant was shown at South Kensington at the time. The flower is very distinct from other varieties, the petals being exceedingly broad, and with the sepals are pure white. The lip is slightly contracted and reflexed near the tip, which is of a fine purplish crimson hue, the throat being boldly veined with a richer tint of the same colour, giving the flowers a particularly handsome appearance in contrast with the white sepals and petals. A variety was shown which is believed to be *L. anceps Sanderiana*, and is something like *Dawsoni*, but inferior to it in beauty, the colour of the lip being paler, and the veins less distinct. *L. anceps Hilliana* has white flowers, the lip yellowish and tinged with rose at the side. *L. anceps rosea* has a rose tint suffusing the lip and petals, and *L. Williamsiana* has white flowers, the lip yellow in the centre, and the throat well streaked with crimson. An unnamed variety of *L. anceps* with purplish sepals and petals, and a broad, square, dark crimson lip, was preferred by some to *L. Barkeri*. Several other varieties have received names such as *delicata*, *grandiflora*, *Percivalliana*, *vestalis*, and *Veitchiana*, some of which are distinct and handsome, especially the last-named, which is also well grown in Baron Schröder's collection. In addition to the *Lælia* flowers Mr. Ballantine had a raceme of *Odontoglossum crispum* Bonnianum, which has neat rounded flowers of moderate size, white with a bluish tint, each sepal having one or two bold round blotches of brown near the tip.

De B. Crawshay, Esq., Rosefield, Sevenoaks, showed a small collection of Orchids, conspicuous amongst them being *Sophranitis grandiflora* splendens, a highly coloured variety, with flowers 2½ inches in diameter. *Lælia anceps blanda*, with blush sepals and petals and a crimson lip; *L. Crawshayana*, crimson; *L. anceps Williamsiana*, the pale golden *Odontoglossum aureum*; and *O. crispum Stella*, a white variety, with spreading sepals and petals were also noticeable. C. Dorman, Esq., The Firs, Laurie Park, Sydenham, exhibited a curious little Brazilian Orchid, *Promenaea stapelioides*, the flowers small and creamy white, the lip strangely dotted with maroon, like some of the *Stapelias*, to which it owes its name. *Odontoglossum Inseayi*, from the same source, is a fine coloured variety, with flowers of great size; but *Cypripedium insigne* Dormanianum did not possess any remarkable characters, though the *Odontoglossum tripudians* superbum, which was certificated, is an extremely handsome Orchid, and amply deserved the honour. Mr. H. James, Castle Nursery, Lower Norwood, had a flower of *Cattleya Trianae* Measuresiana, with broad petals, a brilliant crimson lip, and a gold throat. A cone of *Macrozamia Dennisoni* over 2 feet in length was shown from the same nursery. The New Plant and Bulb Company, Colchester, sent a flower of a pretty light pink *Cattleya*.

**Primulas.**—Messrs. James Veitch & Sons, Chelsea, were awarded a bronze Bannian medal for a group of Primulas comprising about 100 plants, representing several varieties of approved merit. The Queen is a white form, of good habit, and bearing large pure flowers in compact trusses. Improved White, with rather larger flowers, is said to be a selection from The Queen. Improved Blue is one of the best of the so-called "blue" Primulas. *Primula sinensis cristata* fl.-pl. is a double white-flowered variety, with round crisped leaves. The brilliant Chiswick Red was also well shown. Messrs. H. Cannell & Sons, Swailey, exhibited blooms of their principal Primulas, most diversified in colour and distinguished by their admirable substance.

**Tea Rose Sunset.**—To indicate the floriferous character and usefulness of this Rose Messrs. Paul & Son, Cheshunt, exhibited a number of buds and flowers such as they are still cutting freely from the plants in pots under glass. The colour is a pleasing bronzy yellow, the blooms are neat and in the buds are excellent for buttonholes or bouquets, possessing moreover a powerful fragrance. It is very highly commended for culture wherever flowers are in much demand.

**Late Chrysanthemums.**—Mr. John Walker, Thame, Oxon, had several stands of late Chrysanthemum blooms which, though not of the size that exhibitors like to see, were such as would be highly prized in gardens where much floral decoration has to be done. The varieties were Fair Maid of Guernsey, Ethel, Peter the Great, Père Delaux, Elaine, and Jardin des Plantes. Mr. Walker states that he strikes the cuttings in March, and when placed under cover the plants are grown in a north house, where they come on slowly until wanted. For all the exhibits named votes of thanks were accorded.

### PLANT CERTIFICATED.

*Odontoglossum tripudians superbum* (C. Dorman, Esq.).—The finest variety of *O. tripudians* that has yet been obtained. The flowers are over 3 inches in diameter, the sepals oval shining brown with a yellow tip, the petals blotched with brown on a yellowish ground and tipped with the same hue. The lip is broad, fringed and blotched with bright purple.

**SCIENTIFIC COMMITTEE.**—Dr. M. T. Masters in the chair.

*Odontoglossum bicktoniense* with *Foliaceous Bracts*.—Mr. O'Brien showed a peduncle about 5 feet in length, with the upper bracts leafy. He attributed it to a check upon the reproductive energy which the plant had received, in consequence of which the vegetative system had been encouraged, as seen in the lengthened stem and leafy bracts.

*O. Andersonianum*, *Synanthy* of. —He also showed flowers of this species in a synanthic condition, with two lips, two columns, &c.

*Nerine Hybrid*.—He also exhibited pink flowers of a so-called *N. cinnabarina* raised by himself; it was referred to Kew for identification.

*N. flexuosa Hybrid*.—He showed a leaf about 16 inches long and 2 inches broad, of a hybrid between *N. flexuosa* and *N. Fothergillii*, both of which have much narrower leaves, showing the effect of crossing.

**Mahwah Flowers, Sugar in.**—Professor Church gave an interesting account of his researches into the chemical constitution of the sugary corollas of *Bassia latifolia* of India. It was said that it would supersede the use of Beetroot and the Sugar cane; but, he remarked, this would depend upon the character of the sugar. He had analysed some samples of the sun-

dried flowers, and found they yielded 56 per cent. of sugar and 15 per cent. of water; but a further analysis showed that sucrose (cane sugar) was only present in the proportion of 3·2 per cent., while glucose (laevulose and dextrose) yielded 52·6 per cent. Hence it cannot possibly be a substitute for Cane or Beet sugars. Of nitrogenous matters the flowers contained 2·2 per cent. The usual proportions of useful nitrogenous food should have 1 part of flesh-formers to 5 saccharine; but in the case of *Bassia* it was only 2 to 55. He further remarked that in the nectaries of nearly all British flowers the sugar was Cane sugar; but in young Grasses the sugar was glucose, and it was not until the lower leaves had begun to turn yellow that the glucose was converted into sucrose or Cane sugar. In the case of the Mahwah the sugar resides solely in the corolla; a fair size tree will yield about half a ton of fresh flowers; the seeds contain an edible oil.

A vote of thanks was unanimously given to Professor Church for his interesting communication.

*Macrozamia Denisoni*.—A fine male cone of this Australian plant (about 2 feet high and 8 inches in diameter at the base) was sent by Mr. H. James as the first instance of its flowering in this country.

*Begonia species*.—A small-flowered species with white blossoms and much-divided leaves was sent by Sir Trevor Laurence, which had come up with an Orchid. It was referred to Kew for identification.

*Griselinia littoralis abnormal*.—Dr. M. T. Masters showed shoots in which the axillary buds had become "uplifted," so as to be "extra axillary." On examining the buds microscopically, he observed that the bases of the leaves are at first horizontal, but that they subsequently became uplifted too, while the stem assumed a more flattened character.

*Hybrid Potatoes*.—Mr. W. G. Smith forwarded specimens of "hybrid" Potatoes obtained by the method of introducing "plugs" with eyes of one sort into other sorts, as described by him in the *Gardeners' Chronicle*, on "Potato Grafting" (January 9th, page 54). He also forwarded drawings of various sorts illustrative of the results obtained. Dr. Masters observed that both botanists and gardeners had questioned the possibility, but that his own experiments, as well as Mr. Smith's, had completely disproved the assertion. Mr. Henslow remarked that a gentleman in Warwickshire twenty-five years ago had tried it by binding together two halves of a red and white Potato, and that the resulting produce was intermediate in colour. Mr. O'Brien said that the attempts to unite bulbs of Lilies had as yet completely failed.

*The Climate of Cornwall*.—The Rev. George Henslow drew attention to a communication from the Hon. and Rev. J. T. Boscawen in the *Gardeners' Chronicle* for January 9th (p. 55), in which the author alluded to the great variations of temperature and the corresponding differences in the effect upon vegetation in his garden at Lamorran. Mr. Henslow observed that the peculiarities could be at least partly explained by a study of the distribution of cold in England. Mr. Boscawen compared that of Lamorran with the temperatures of Kent, Sussex, and Liverpool. It will be found that isotherms of 30° or 20°, as the case may be, often run closely parallel with the coast line; or else, running parallel from Cornwall to nearly the meridian of 0°, it then turns abruptly northwards, cutting the E. coast at Newcastle. Hence it not unfrequently happens that Kent and Sussex are just without the isotherm which includes Cornwall. Similarly, following the isotherm round the west coast, an indentation occurs around Liverpool in consequence of its being on the great western plain (continuous with the Severn Valley). The next point to be observed is that the internal distribution of areas of low temperatures correspond with the more elevated tracts, showing that the lowering of the temperature is due to radiation. One of these "local centres" always occurs over the elevated region of Cornwall and Devonshire. As the Cornish tableland extends far down towards the Land's End, the effects of this cold area are doubtless felt at Lamorran. On the other hand, the S.W. coast reaps the benefit of the gulf stream, so that in ordinary winters Fuchsias, Escallouias, Hydrangeas, &c., are not cut at all. Lastly, individual causes of influence, such as depressed spots, where temperatures will be lower than on adjacent heights, exposure to W. or E., as the case may be, &c., as well as differences of soil, in addition to the character of the subjacent rock, which may be a good or bad conductor of heat. Taking all the above facts into consideration, Mr. Henslow suggested they were amply sufficient to account for the anomalous features of Lamorran.

*Plants Injured by Frost in Cornwall*.—The Hon. and Rev. Mr. Boscawen forwarded leaves and shoots of various shrubs, Camellia, Hydrangea, &c., more or less blackened by the late frost at Lamorran, as described by him in the *Gardeners' Chronicle*.

### JUDGING.

"CONSULT the Judges and act accordingly," is as far as I can see the only remedy advanced by "W. S.," page 590, towards the solution of the difficulty referred to by me at page 565, and a very weak and unsatisfactory one it appears to me to be, simply because it leaves the evil untouched and unremedied.

My desire was to point out the best and least offensive method of rectifying palpable and undoubted errors in judgment which unfortunately do sometimes, though seldom, occur at exhibitions. Of course "the Judges would be consulted," but what I proposed was a Court of Appeal in extreme and exceptional cases after the Judges had refused to alter their decisions. The Committee, even then, would not have power to reverse nor in any way interfere with the awards conferred, but exercise a discretionary prerogative by giving or withholding, as they thought fit, an extra or consolation prize to the injured exhibitor. "W. S." would cruelly allow the sufferer to go uncompensated without permitting the slightest chance of appeal, which to me seems an inconsiderate, unjust, un-English-like method of treating the question.

As to such a practice being likely to induce exhibitors unduly to clamour for prizes, I have too good an opinion of their sense of honesty and propriety, nor do I think it would have a prejudicial effect on Judges. On the contrary, it would, I think, act beneficially by inducing them to be even more careful than they hitherto have been. "W. S.'s" estimate

of the ability as judges of many of the gentlemen who form flower show committees may be different to mine, but in my experience I have never yet met a committee which has not comprised some amateurs and professionals who were in every respect qualified to act as judges, but for obvious reasons they would not act in that capacity at home, hence the necessity of engaging others. These reasons, however, would in no way debar them, either morally or legally, from acting in the capacity I have mentioned, as arbitrators in exceptional and extreme cases.

That such cases do sometimes occur is undeniable. Are they to continue without an attempt to remedy them? If not, what are the best means to adopt? The suggestions I ventured to make may not be perfect, but they do not appear likely to infringe the rights or privileges of either committee, exhibitors, or judges, and practically they would cause but little irritation to any concerned, while they would at least partially remedy the evil instead of leaving it, as it has been occasionally, a source of discord and contention.—T. CHALLIS.

### REVIEW OF BOOK.

*The Praise of Gardens: a Prose Cento, collected and in part Englished by ALBERT F. SIEVEKING; with Proem by E. V. B.* London: Elliot Stock.

THIS is one of the series of books issued by Mr. Elliot Stock in the quaint style of typography and paper with which readers fond of good and wholesome literature issued by that gentleman are already familiar. The object of the editor appears to have been to collect from the best sources the encomiums which the greatest writers, both ancient and modern, have bestowed upon gardens and gardening. We, who have been so long engaged in the pursuit, and derived both health and pleasure from the prosecution of it, are not surprised to find such a treasury of praise as Mr. Sieveking has collected in this volume; but there are many who cannot realise the enjoyment a garden gives, and to these we commend a perusal of this work.

The following extract from H. race Walpole on "Modern Gardening" will illustrate the contents of the work:—

A cottage and a slip of ground for a Cabbage and a Gooseberry bush, such as we see by the side of a common, were in all probability the earliest seats and gardens: a well and bucket succeeded to the Pison and Euphrates.\*

As settlements increased, the orchard and the vineyard followed; and the earliest princes of tribes possessed just the necessities of a modern farmer.

Matters, we may well believe, remained long in this situation; and though the generality of mankind form their ideas from the import of words in their own age, we have no reason to think that for many centuries the term *garden* implied more than a kitchen garden or orchard. When a Frenchman reads of the Garden of Eden, I do not doubt but he concludes it was something approaching to that of Versailles, with clipped hedges, berceaux, and trellis-work. If his devotion humbles him so far as to allow that, considering who designed it, there might be a labyrinth full of Æsop's fables, yet he does not conceive that four of the largest rivers in the world were half so magnificent as an hundred fontaine full of statues by Girardon. It is thus that the word *garden* has at all times passed for whatever was understood by that term in different countries. But that it meant no more than a kitchen garden or orchard for several centuries, is evident from those few descriptions that are preserved of the most famous gardens of antiquity.

In the paintings found at Herculaneum are a few traces of gardens, as may be seen in the second volume of the prints. They are small square inclosures formed of trellis-work and espaliers,† and regularly ornamented with vases, fountains, and Caryatides, elegantly symmetrical, and proper for the narrow spaces allotted to the garden of a house in a capital city. From such I would not banish those playful waters that refresh a sultry maneion in town, nor the neat trellis, which preserves its wooden verdure better than natural greens exposed to dust. Those treillages in the gardens at Paris, particularly on the Boulevard, have a gay and delightful effect. They form light corridors, and transpicuous arbours through which the sunbeams play and chequer the shade, set off the statues, vases, and flowers, that marry with their gaudy hotels, and suit the galant and idle society who paint the walks between their parterres, and realise the fantastic scenes of Watteau and Dufé.

From what I have said, it appears how naturally and insensibly the idea of a kitchen garden slid into that which has for so many ages been peculiarly termed a garden, and by our ancestors in this country distinguished by the name of a pleasure garden.

A square piece of ground was originally parted off in early ages for the use of the family—to exclude cattle and ascertain the property, it was separated from the fields by a hedge. As pride and desire of privacy increased the inclosure was dignified by walls; and in climes where fruits were not lavished by the ripening glow of nature and soil, fruit trees were assisted and sheltered from surrounding winds by the like expedient; for the inundation of luxuries which have swelled into general necessities, have almost all taken their source from the simple fountain of reason.

When the custom of making square gardens enclosed with walls was thus established, to the exclusion of nature and prospect, pomp and solitude combined to call for something that might enrich and enliven the insipid and unanimated partition. Fountains, first invented for use, which grandeur loves to disguise and throw out of the question, received embellishments from costly marbles, and at last to contradict utility, tossed their waste of waters into air in spouting columns. Art, in the hands of rude man, had at first been made a succedaneum to nature; in the hands of

\* Two of the four rivers enclosing Paradise, the others being Gihon and Hiddekel.

† At Warwick Castle is an ancient suit of arras, in which there is a garden exactly resembling these pictures of Herculaneum.—Walpole's Note.

ostentatious wealth it became the means of opposing nature; and the more it traversed the march of the latter, the more nobility thought its power was demonstrated.

Canals measured by the line were introduced instead of meandering streams, and terraces were hoisted aloft in opposition to the facile slopes that imperceptibly unite the valley to the hill. Balustrades defended these precipitate and dangerous elevations, and flights of steps rejoined them to the subjacent flat from which the terraces had been dug. Vases and sculpture were added to these unnecessary balconies, and statues furnished the lifeless spot with mimic representations of the excluded sons of men. Thus difficulty and expense were the constituent parts of those sumptuous and selfish solitudes; and every improvement that was made was but a step farther from nature. The tricks of waterworks to wet the unwary, not to refresh the panting spectator, and parterres embroidered in pateras like a petticoat, were but the childish endeavours of fashion and novelty to recougle greatness to what it had surfeited on.

To crown these impotent displays of false taste, the sheers were applied to the lovely wildness of form with which nature had distinguished each various species of tree and shrub.

The venerable Oak, the romantic Beech, the useful Elm, even the aspiring circuit of the Lime, the regular round of the Chestnut, and the almost moulded Orange tree, were corrected by such fantastic admirers of symmetry. The compass and square were of more use in plantations than the nurseryman. The measured walk, the quincunx, and the etoile imposed their unsatisfying sameness on every royal and noble garden. Trees were headed and their sides pared away; many French groves seem green chests set upon poles. Seats of marble, arbours and summer-houses terminated every vista, and symmetry, even where the space was too large to permit its being remarked at one view, was so essential, that, as Pope observed:—

"... Each alley has a brother,  
And half the garden just reflects the other."

Knots of flowers were more defensibly subjected to the same regularity. Leisure, as Milton expressed it,

"In trim gardens took his pleasure."

In the garden of Marshal de Biron at Paris, consisting of fourteen acres every walk is buttoned on each side by lines of flower-pots which succeed in their seasons. When I saw it there were nine thousand pots of Asters, or *La Reine Marguerite*.

We do not precisely know what our ancestors meant by a bower, it was probably an arbour; sometimes it meant the whole frittered enclosure, and in one instance it certainly included a labyrinth. Rosamund's bower was indisputably of that kind, though whether composed of walls or hedges we cannot determine. A square and a round labyrinth were so capital ingredients of a garden formerly that in Du Cerceau's architecture, who lived in the time of Charles IX. and Henry III., there is scarce a ground plot without one of each. The enchantment of antique appellations have consecrated a pleasing idea of a royal residence, of which we now regret the extinction. Havering in the Bower, the jointure of many dowager queens, conveys to us the notion of a romantic scene.

### NOTES ON SOWING EARLY PEAS.

SOME recommend sowing Peas in November, and many are successful with them, but I cannot understand why sowing in succession should not go on in December, January, February, and onwards. The soil and atmosphere are not much warmer in November than in the months named, and the seed germinates as freely, and the plants grow as quickly, in January as they do in November. For this reason I am not very favourable to November-sown Peas. They are often ready for use earlier than any which are sown in March or thereabouts, but they are no earlier than January-sown ones, and I am as much in favour of sowing now as in November. The plants from seed put in now will be quite as high by March as any of them, and while November-sown Peas often come to a standstill in January or February, those sown later generally growing slowly.

Where there was seed sown in November I would recommend several rows more to be sown now, and where sowing was omitted before, they may still be put in with the full understanding that no time has been lost. Only the round-seeded varieties, such as *William I.* and *Ringleader*, must be sown thus early. The wrinkles will not bear the cold damp soil, and should never be sown until March at least. If a good row of *Ringleader* is sown the first or second week in January, and the same early in February, the young crops in March and onwards will be as satisfactory as anyone can desire. Rich, rather light soil, suits them best now, and a sunny position is very desirable. Many devote a great deal of time, with much space and heat to raising early Peas under glass in the spring months, and so long as they are kept under glass they go on well, but when planted out in the open soil they are almost sure to receive a check, and this is sometimes so severe, that by May the under-glass-raised Peas are the worst in the garden. Altogether, in my opinion, this system does not pay, and it ought to be abandoned in favour of early sowing in the open air. We have over and over again tried to do great things with these forced Peas, but I cannot remember a single instance where they were really first-class, especially in quantity, and every year we feel more and more convinced that to give the best attention to those sown early in the open is the best way of securing abundance of early pods and profitable crops.—A KITCHEN GARDENER.

### SESBANIA GRANDIFLORA.

UNDER the genus *Sesbania*, which is included in the great family Leguminosæ near *Swainsonia* and *Clianthus*, are grouped ten or a dozen species that are little known in gardens, though one of them, *S. ægyptiaca*

has been in cultivation for 200 years. They are mostly yellow-flowered shrubs or annuals, with long pinnate leaves, and have a rather graceful, ornamental appearance. Much the finest of all, however, is *Sesbania grandiflora*, which is represented in fig. 7, kindly lent us by Messrs. Cheal & Sons, Lowfield Nurseries, Crawley. This has flowers considerably larger than any other species, and being pure white they are very handsome. It is one of the four *Sesbanias* found in Australia, but differs so much in the size of the flowers and in the proportionately narrower petals that some have assigned it separate generic rank under the name of *Agati*. In the "*Flora Australiensis*," however, Mr. G. Bentham states that it only differs in these characters, and that in all other respects it is identical with the *Sesbanias*, amongst which he places it. In a note appended to the description given in the work named, a red variety is mentioned as follows:—"The red-flowered variety, *S. coccinea*, or *Agati coccinea*, is not amongst

Fig. 7.—*Sesbania grandiflora*.

the Australian species I have seen. Both varieties are frequent in India but perhaps only about villages and other places where they have been planted; they both appear to be really indigenous in the Archipelago." It is also interesting, as noted by Mr. Bentham, that "of the four Australian species three are the commonest Asiatic ones, two of them extending also over tropical Africa," and only one, *S. simpliciuscula*, is confined to Australia.

*S. grandiflora* is a native of the western part of the great southern continent, and in consequence succeeds under cultivation in a greenhouse temperature. The soil should be moderately light, an admixture of leaf soil or peat with turfy loam and sand being suitable.

### GLADIOLUS BRENCHEYENSIS.

THERE are few gardens where this useful old favourite is not grown often in bedding arrangements, but more generally in the mixed border.

Another way in which I find it useful is as a pot plant, and I have often wondered why it is so little grown as such, especially for use in "groups for effect" at summer exhibitions, where its brightly coloured spikes have a telling effect associated with Palms, Ferns, Crotons, Caladiums, and other ornamental-foliage as well as flowering plants.

The culture is not difficult, but the time of potting must be guided by

the time they are required to flower, the average length from each period being about sixteen weeks. I usually pot strong corms singly into 32-sized pots, and these mostly throw two spikes. After the potting is completed they are placed in the greenhouse, and little water is required until they are starting freely, when they are gradually hardened and placed out of doors in a position sheltered from strong winds. I do not plunge them, but they are well attended to with water, and when roots are plentiful I give liquid manure moderately at first, increasing the strength as the flower spikes advance, which are also neatly staked. As the flowers show colour the plants are taken under glass, and grown in this way I find them much appreciated for decorating the drawing room and other places in the mansion.—J. COPSON *Down Ampney*.

### TREES AND SHRUBS FOR THE SEASIDE—ELDERS.

At the annual general meeting of the English Arboricultural Society, on Saturday, 28th ult., in the Farmers' Club Room, Newcastle, Cadwallader J. Bates, Esq., of Heddon, in the chair, Mr. B. Cowan, South Shields, read the following paper, entitled "Trees and Shrubs Suitable for the Seaside, and where Alkali and other Gases are Prevalent."

When I was first appointed to my present position I felt somewhat the difficulty in knowing what to do for the best. The position was one of the most exposed, situated about 80 feet above the sea level, and one portion sloping towards the sea, the other portion sloping to the west. So when an east wind, or rather north-east wind came, and the trees beginning to burst forth in leaf, we suffered tremendously. Still, strange to say, we prefer the east winds to the west, as then we are within easy distance of two or three chemical factories which we get full benefit. I purpose speaking first of the plants I found to do best on a rugged eminence same as ours, of which there are many other situated similar on the north-east coast. "The part referring to alkali and other noxious gases I shall leave to the last and treat separately, and if anyone have the two evils to contend against, certainly his hands are full."

**Soil.**—The soil first is of the greatest importance, as it is necessary the soil be good, well drained to increase rapid growth, so as to cause shelter which is of the utmost importance. If the soil is clayey I would strongly recommend trenching and ridging. The latter I believe to be of great importance. Our soil here was clay fit to make bricks, every spadeful of it. In the autumn of 1880 we started to trench about two spades deep. The men frequently had to dip their spades in water to get the clay off. The bottom was slightly stirred so as the water would escape more readily. The manure we used was solely the Corporation manure, which we received free of cost, and delivered as well, being at an easy distance from the town. This was put 4 or 6 inches at the bottom. It will be scarcely needful to detail what this manure contains. It is generally night soil, with a preponderating quantity of ashes, and all vegetable and domestic refuse. Our object was, if possible, to lighten the clayey nature of our soil, and render it more porous. When we formed the ridges another copious application of manure was given. The ridges were 15 to 18 inches in perpendicular height. The object of this was to expose as much of the clayey soil to the action of the atmosphere as possible. Betwixt these ridges was put sea sand. We went to this slight expense as the manure did not cost us anything. It will perhaps be remembered that the winter of 1880-81 was very severe. This acted to our advantage in getting the soil into a friable condition for planting, which was done at the end of March, the proper time for cold ungenial soils. After the process mentioned I could take the clayey soil that had been directly exposed to the action of the atmosphere by the ridging method in my hand and squeeze it into fine powder, like any ordinary soil. I am a thorough advocate that clayey farming or gardening can be made to pay by similar methods, such as I have mentioned. Part of the borders were not planted this year. We trenched and ridged them the second year; these were in excellent condition, as we arranged to make the ridges betwixt those of the previous year. I feel convinced the ground, when these trees were put on it, would have grown excellent Strawberries or similar plants that like rich ground. Each year we still give a liberal dressing of the same manure.

**Planting.**—My great difficulty lay in making a judicious selection, as not a vestige of any kind of plant was to be seen except here and there a straggling plant of the common Elder, *Sambucus communis*. So as not to cause too much expense, I thought I would first make only a small selection. Where the ground is on a level with the sea it is not so bad as when the ground you wish to plant is on an eminence, considerably above the sea level. Golden Elders and their varieties are good; amongst Poplars Ontario is the best, and the Black Italian succumbing much more easily than the Ontario. Sea Buckthorn and *Ligustrum ovalifolium* will be sufficient to start with. *Ribes sanguinea* and Lilacs we planted here, but they nearly died to the ground line. They have, since our trees have grown, done much better, and I have no fear as our trees grow they will increase the value of other flowering shrubs. I cannot say too much in praise of the Golden Elder. I am often surprised it is not grown in gentlemen's gardens a good deal more, the foliage being of such a delicate golden colour, and associates well with Coniferae or ornamental shrubs. I have never seen it do better anywhere than with us, it seems to like strong rich soil and fully exposed to the direct rays of the sun. Among the many varieties we have here none grows so readily and rapidly as the Golden one. Last year we had a large oblong bed of Dahlias and *Chrysanthemum inodorum flore plenum* edged with it, which was effective and much admired. We also had a ribbon border 100 yards long; the back row was Golden Elders, second row *Vesvius Pelargoniums*, and third edged with blue Lobelias. Next year we will add *Dactylis*, so that the white may contrast with the yellow. The Golden Elders are plants one year old. We find no difficulty in keeping them low enough by an occasional pinch during summer. We have 10,000 plants of Golden Elders, and cartloads of cuttings. We planted here in our borders, in the background the common Elder thickly, 2 feet apart, then, in the front, rows of Golden Elder, *Ligustrum ovalifolium*, and one common Elder alternately, and, occasionally, here and there, a plant of the Sea Buckthorn, which had thus a striking and beautiful appearance blended with the Golden Elders and Privet. The

Buckthorn is slow of growth, but the colour is so pretty, and its Fern-like appearance renders it at once an attractive plant for grouping. Amongst these were placed at intervals plants of Poplar Ontario; as the Elders have grown and become thick the Poplars have got well away. The Elder commences growth so early that if they are planted thickly towards the sea, they would in my opinion act as a shelter for most flowering trees and shrubs.

Mr. Clark, who was gardener for thirty years at Whitley Park, has made his place quite a wonder. He never could grow anything until he got shelter, and this was effected by erecting wooden trellises on the tops of the walls. Previous to that the trees were broken at the tops quite level with the wall-top. This is also apparent in other portions of the coast. Farther north towards Cresswell, Scotch Fir plantations are just nipped at the angle; the plantation inclines towards the sea. Mr. Clark found after getting belts of Elders up the trellis at the wall tops, Sycamores, Elms, Hollies, *Pinus austriaca*, *Cotoneaster microphylla* and *Simonsii*, the Tamarisk, *Aucuba japonica*, and the *Euonymus*, the latter doing excellently. Rhododendrons, Hollies, and other deciduous and evergreen shrubs have done well. In some parts of the village where shelter is afforded Horse Chestnuts have done well. It is generally the cold blasts with a north-east wind prevailing that do the harm. Willows have not succeeded very well with me; the best, I think, is *Salix ruhra*. If planting again in so exposed a place as Westoe Cemetery, I should prefer to keep back the Willows till the Elders were up a little, which would be in the course of two or three years.

**Pruning.**—This forms an important part of the winter's work. In each year we pruned down the young Elders two or three eyes, as the strength of the shoot will allow. This causes them to spring very thick. In one avenue we had running east and west, 300 yards long, it is now scarcely possible for the sun to penetrate during summer, forming a cool and pleasant promenade for the visitors. We also add copious quantities of manure dug over early, so as the benefit of the winter may not be lost in rendering the soil more friable. The shoots that many of the Elders here made last year have been, some of them, 10 feet long, and have not been planted five years till spring next, and in the summer the avenue is from 12 to 15 feet high.

**Propagating.**—We annually propagate great quantities of the Golden Elders. We find them grow more readily than even the common Elder. In pruning, the cuttings are taken and heeled in and made on wet days. We generally cut them in lengths of 6 or 8 inches, reserving two eyes to them; but even this is not necessary, as they will grow like Vines from one eye. The end of the shoots, if not sufficiently ripe, are generally cut off; any time between November and March we put them in as it may suit our convenience. Our forefathers attributed many medicinal qualities to the Elder as well as the excellent wine that is made from the berries, which is supposed to contain a narcotic. Boerhaave, the great physician, is said to have rendered homage to the Elder for the above qualities, and never to have passed an Elder without taking his hat off. The leaves are narcotic, purgative, and acrid; the flowers act in decoction as a diaphoretic and are used to flavour vinegar, while in some of the French provinces the peasants strew the leaves among casks of Apples to give them an agreeable flavour, while others aver the berries prove poisonous to poultry, especially to turkeys. Elder flower water is also used for flavouring confectionery of various kinds. The following are among the best varieties: *Sambucus aurea*, gold-leaved; *Sambucus argentea*, silver-leaved; *Sambucus laciniata*, Parsley-leaved. The latter looks splendid with the Golden one. *Sambucus fastigiata* is pyramidal in form and looks splendid by itself. If this variety was only golden it would be one of the most attractive plants we have; it grows the same as an Irish Yew. *Sambucus canadensis*, the white-berried; *Sambucus rotundifolia* is striking in its characteristics; pubescens and racemosa are varieties also well worth growing. The scarlet-fruited is a very fine variety, but does not do over-well here, as the Elder scarcely ever fruits with us, and is only inferior when it does so. We have a variety which becomes very pretty in the autumn. The foliage assumes between a metallic and crimson shade, the wood becoming the same way; we are propagating all we can of this variety. Elders are really the predominant feature for the seaside. The Oval-leaved Privet has never yet kept its leaves during the winter. It was longer in shedding them last year, and as they grow older I hope they will remain in their natural state evergreen, as that is everything in a plant being developed and strong, as they will stand a good deal more bleak winds and even the effect of alkali when they are established. It is, therefore, prudent never to insert plants that are high. Poplars, for instance, should not be more than 3 or 4 feet high at the very most, and then carefully staked, so as to avoid the great amount of rocking they will naturally be exposed to in a north-east wind. I believe if any shrubs stand without shelter the terrific assail of wind it will be the *Aucuba japonica* and *Cotoneaster microphylla*, both of which, in the Marine Park, South Shields, are standing when all other shrubs have failed. Mr. Fred. Goodwin, the Manager of the Cliff Bridge Company, Scarborough, finds that trees one to two years old are best to plant, which have been carefully transplanted in the soils we have mentioned. After they have got up, he has found deciduous and flowering plants of the ordinary kinds do well. Hollies, *Aucubas*, *Escallonia*, Privet, and *Cotoneasters* he shelters from the east wind from November to May. He also finds where his grounds are not immediately facing the sea, but sloping to the west or south, that he can grow every kind of plant much better.

**Alkali and other Injurious Gases.**—The position of our place is almost unique, exposed to all the cruel blasts of our north-east coast, and yet I have generally hoped that in the spring the wind may continue in that cruel quarter, as it has been our only hope of getting our trees into leaf. When the wind changed we were sure to have the chemical fumes, which are most injurious, especially in the initial state of the growths of the trees. Imagine a west wind which ought to cheer the hopes and buoy up the spirits of anyone desirous of seeing his trees come out in full foliage, causing all his hopes to vanish. Such was the case till within this last year or so, when, by some change in the process of the chemical factory it has been considerably mitigated, which has not been slow in showing the rapid growth on that part of our grounds facing to the west; but again, just lately, there is started a large brick kiln, within 50 yards of our main avenue, which no later than September destroyed one side of the avenue. The kiln is on the south side of the avenue. The wall is about 7 feet high. On the north side all was killed nearly to the ground line, especially *Ribes* and Lilacs, which

suffered much more than the Elders, the Golden one standing really the best. In this case we were given damages without any litigation whatever. When you have to apply to chemical companies for damages litigation is troublesome to whoever is in charge, and causes much thought and care, as chemical companies generally know how to look after their interests. What I have generally done here is to use litmus paper. Take the wind once or twice a day, you can generally tell by your nose if alkali sulphuric acid is present in the air. At the same time when the wind is blowing on your place see that smoke is issuing from the chimneys, put out your litmus paper. If you use the red and it turns blue of course alkali is present. If the blue turns red, then it is sure presence of sulphureous acid, which kinds are both injurious to vegetable life. Do not leave the paper out too long, as there is always carbon in the air, which would naturally turn the red paper blue. We are situated about three-quarters of a mile from the factory which did us the most harm. The distance that alkali will do harm depends considerably on the height of the chimney. The higher it is the further the alkali travels before it spreads and does harm. A certain well-known chemical company, close to their factory, bought all the ground and made it into gardens, and when any of the adjoining farmers complained they brought them to see how their gardens were flourishing close to their factories. Of course, the height of their chimneys were such as to carry the gases away some distance, but workmen have got a habit lately of letting the gas out of the chambers at night for their own ease and comfort. This often causes the most unpleasant results to vegetation. I have found plants growing near the ground line, but not nearly so much affected. Plants, after a dose of it, look as if they were burned, and in the early stages of growth is worse, and are not apt to get over it for that year. There is also another strong fact. Plants and trees that have been long established will stand it much better than those of two or three years old, which have not the strong hold of the ground, so that when damaged to the ground line, there is one fact which goes far to prove what I have said as to the length or distance chemical fumes will be injurious is that we have on the south avenue I mentioned, where the walk is 9 feet, the trees on one side are killed, that is the nearest one, and the other side they were doing remarkably well. The same kinds of deciduous trees that I have mentioned do to plant where alkali abounds, but Elders are the best. In fact a good plan would be to insert Elder cuttings of sorts 3 or 4 feet thick in the direction the alkali comes, so as to break the effect of it. Nothing does so well as the Elder. It will thrive if the soil is well prepared, as has been described, so as to cause a quick growth, and even where alkali is strong a pleasing effect may be made of the few kinds of trees I have briefly mentioned, providing they are carefully looked after. In many open spaces we plant Elders to relieve the monotony; these we can either train as pyramids or pyriform as we may wish. We generally place the Golden and common alternately, which has a most pleasing effect.

### CŒLOGYNE CRISTATA.

THIS Orchid is remarkable for its easy culture, freedom of flowering, and endurance of a cool dry atmosphere when in flower, being indeed one that may be removed to the drawing-room or boudoir without fear of injury, and forming a most attractive plant for a period extending over three weeks. It produces drooping racemes of pure white flowers 3 or 4 inches in diameter, with a large blotch of rich yellow in the middle, the veins having a golden crest-like fringe, and being withal fragrant it is in every respect desirable.

It may be grown in pots, in baskets, and on blocks. Plants in small pots or saucers (perforated), and baskets, the latter when neatly mossed being suitable for the table. The pots or baskets should be well drained; half the depth may be occupied with crocks, and the material may consist of equal parts live sphagnum, rough pieces of peat, and charcoal, with a sprinkling of sand, raised in a moderately high cone in the centre, and well pressed down. The pseudo-bulbs may be placed about their own diameter apart, and pegged to the surface, using galvanised pegs, which are quickly made of No. 14 gauge wire. The pseudo-bulbs should not be buried, their base merely resting on the surface of the material. A little live sphagnum may be placed between them, which gives a neat finish. The time to repot or resurface is just after the flowering is over, or, as a rule, the early part of February. In resurfacing the old sphagnum should be picked out, being careful not to damage the bud at the base of the pseudo-bulbs, and supply fresh lumpy peat and live sphagnum.

I prefer to grow this plant on blocks of wood. The size used is 18 inches long and about 9 inches diameter, taking off about one-third longitudinally, so as to form a flat side for suspending against a wall or the end of a house. If the blocks can be suspended clear there is no reason why they should not be round and covered with the pseudo-bulbs, so as to allow little if any more than their own diameter between them. The blocks are of Elm stripped of the bark. I cover them with a little rough peat, then introduce the Cœlogyne along with the sphagnum, and secure with galvanised nails and copper or galvanised wire. They are suspended anywhere in the stove where there is room and light. The effect of these blocks when the Cœlogyne is in bloom is charming. The blocks are easily kept moist, as the water needs only to be poured on the top of the blocks, and there is no fear of water lodging in the young shoots and causing their decay. Water will, of course, find its way to the bottom of the block, so that the upper part will be driest, and the watering must be regulated in quantity so as to saturate the blocks as low down only as required.

During growth the plants must not be allowed to become dry, and copious supplies of water are necessary, keeping them constantly wet from the time the plants begin to grow in spring, and I give a light dash from the syringe twice a day after the pseudo-bulbs begin forming. From February to October they require plenty of water, but when they are of good size water only need be given to keep them from shrivelling. Whilst growing a stove temperature is necessary, or that of the Cattle

house, but in winter they may be kept cool or in a temperature of 50° to 55°, though they will do well enough in a stove temperature, only do not keep them very moist, or premature growth may commence.

Cœlogyne cristata does well in an ordinary stove, and excellently in an intermediate house; notwithstanding, it is all the better if encouraged when making growth, as a dry atmosphere causes the leaves to become stunted, and as these are so are the pseudo-bulbs and flowers.

There are at least two varieties—viz., *C. cristata alba* and *C. cristata Lemoniana*, the former being pure white and the other citron yellow.—G.

### NATIONAL CHRYSANTHEMUM SOCIETY.

JANUARY 13TH.

THE Exhibition of late Chrysanthemums provided by this Society at the Westminster Aquarium on Tuesday last proved a welcome surprise to most visitors, for there was a general opinion that the attempt would prove an unsuccessful one. Happily the result indicated in a more convincing manner that it is possible to obtain an exhibition of much beauty at a time which has hitherto been the duldest in the whole year from a horticultural point of view. The Society deserves great praise for their efforts to extend the season of the Chrysanthemum, and the most pleasing success of their first January display will give them encouragement to organise a show on a still more extensive scale another season.

The schedule provided six classes, in which first and second prizes were offered, varying from £2 to 10s., and in several cases third prizes were also awarded. The incurred blooms were the least satisfactory, neither of the classes for twelve or six blooms being well represented, and it is evident that the Japanese varieties must be principally depended upon for late shows of this character. A second prize was awarded to Mr. Bettisworth, gardener to R. Ewing, Esq., Burton Grange, Cheshunt, for twelve incurred blooms, eight being *Miss Marechaux* and four *Princess Teck*. A similar prize was awarded to Mr. J. Walker, Thame, Oxon, for small blooms of *White Venus*, *Duchess of Teck*, and *Jardin des Plantes* in the class for six incurred.

With twelve Japanese R. Falconer Jameson, Esq., Hesse, Hull, secured first honours, showing fine full blooms of *Triomphe de la rue des Chalets*, *Mad. Augustine Gautheraut*, *Sceptre Toulousain*, and *Beud Or*, all bright fresh blooms. Mons. Comte, Japonais, and *Boule d'Or*, in duplicate, were also noticeable for their good quality. Mr. H. Lister, gardener to Lord Brooke, Easton Lodge, Dunmow, was a close second with very bright fresh blooms of *Triomphe de la rue des Chalets*, *Grandiflora*, *Comtesse de Beauregarde*, *Thunberg*, *Meg Merrilees*, *Fanny Boucharlat*, and *Mad. C. Andiguier*. Mr. Bettisworth was placed third with *Ceres* and *Meg Merrilees*, especially fine, and an extra prize was awarded to Mr. Sullivan, gardener to D. B. Chapman, Esq., Downshire House, Roehampton, for a number of varieties, but rather small blooms. The last-named exhibitor was, however, first with six Japanese, showing *Mad. A. Tezier*, *Ceres*, and a *Yellow sport* from *Khediye*, Mr. J. Walter following with small examples of *Peter the Great*, *Elaine*, and *Ethel*.

A class was devoted to a collection of twelve blooms of any Chrysanthemums distinct varieties, and this brought a pretty display. Mr. Falconer Jameson was again the most successful, taking the first place with good examples of *Golden Christine*, *Souvenir de l'Ardennes*, *Marquis de Lorne*, *Triomphe de la rue des Chalets*, *Roseum superbum*, *Jeanne d'Arc*, *Mons. Comte*, *Mad. Berthie Pigmy*, *Pink Christine*, and *Mad. Cabrol*. Mr. G. Bolas, gardener to N. Chandos Pole Gill, Esq., Hopton Hall, Wirksworth, was second, the best blooms being *Mons. C. Hubert* and *Source d'Or*. Mr. Bettisworth was third with *Fanny Boucharlat* in good condition, and the bright yellow large *Anemone Sunflower* was equally fine. An extra prize was awarded to Mr. Walker for small blooms similar to those he had in other classes.

The most effective portion of the display was that in the class for a collection not restricted as to number of blooms or varieties, in which Mr. Joseph Lowe, Uxbridge, won first honours with six boxes, containing twelve dozen blooms. There were two boxes of *Princess Teck*, and the same number of *Grandiflora*, one box of a beautiful bronze and bright red Japanese named *Lowe's Late Bronze*, and a box of mixed varieties, such as *Fair Maid of Guernsey*, *L'Africaine*, *Fulton*, and *Lady Marguerite*. Mr. R. Owen, Maidenhead, was a very close second with fewer blooms, but some were of excellent size and substance, and all were as fresh as possible. The principal sorts represented were *Boule de Neige*, *Belle Paule*, *Ethel*, *Sarnia*, *Mad. Deville*, *Etirole Fleuri*, *Dr. Macary*, *Colibri*, *Fabian de Mediana*, *L'Incomparable*, *Mrs. Mahood*, *Nuit d'Automne*, *Golden Queen*, *M. Delaux*, and *Fanny Boucharlat*. Mr. Bettisworth was awarded an extra prize.

The non-competing exhibits added to the extent and interest of the Show, certificates of merit being awarded to the following:—To Mr. F. Taylor, gardener to Sir John Lubbock, Bart., M.P., High Elms, Beckenham, for a bright and pretty collection; to Mr. E. Beckett, Alderney Park, Elstree, for a collection of handsome blooms representing some of the best varieties; and to Messrs. H. Canuell & Sons, Swanley, for a group of *Primulas* and small *Oranges* in pots, well fruited and most ornamental. Mr. G. Sinclair, East Linton Gardens, Peebleshire, N.B., sent a wreath of *Elaine* which was highly commended, as were also three fine blooms of *Boule d'Or* from Mr. Horrocks, Withington, Manchester. Messrs. W. & G. Drover, Fareham, Hants, showed blooms of a Japanese variety named *Syrin a*, which the Committee would like to see again in the autumn. The florets were blush-tinted, fluted, and incurved, forming a good solid bloom.

There was a good attendance of visitors during the afternoon and evening, and considerable satisfaction was expressed at the Society's first venture in a new direction.

**LARGE SPRING ONIONS.**—For exhibition in July and August there is always a demand for large spring-sown Onions. Here is a good way of securing them. Get some very tough turf, soak it in liquid manure, dry it, then cut it into pieces 2 inches square, make a little hole in the centre of each with the forefinger, drop two or three seeds into each hole, and then place the turves in a layer close together in a shallow box. Shake a very little soil over the turf to fill the holes, and then place the boxes near the glass in a gentle heat. The seed will soon germinate, and a fine

plant with its roots convenient for transplanting will be the result by the middle of March. There is no better way than this of raising a few scores of early plants, and the plan applies capitalily to Leeks and Celery. The transplanting period is the time which tries all early underground-reared vegetables, and the square-turf system preserves the roots well.—M. W.

#### HARDY FRUIT GARDEN.

Do not waste space in the orchard or fruit garden upon inferior sorts of fruit. If you have old trees, ascertain if they are of really good sorts; if not, either grub them up or head back and graft next March. Lists of the best sorts of hardy fruits were given in time for selections for autumn planting. Since then we have repeatedly seen considerable quantities of inferior fruit in the market (especially of Apples) that sold for a mere trifle in comparison to what is paid for choice selected imported fruit. We have also been to Covent Garden and witnessed the opening of barrels of American Apples, and the keen competition of eager purchasers who evidently knew that there was "money" in the venture. The sight was instructive, and we could not but wonder how the fruit-growers of this country—at any rate in the south—could allow Brother Jonathan to come across the Atlantic and forestall them in the market. We again, therefore, before the planting season is over, call attention to some good sorts of fruit which are really profitable in the full sense of the word both for home consumption and for market. We turn first to the best sorts of Kent fruit grown, as enumerated by Mr. George Bunyard, who is a member of the Fruit Committee of the Royal Horticultural Society, and Mr. Charles Whitehead, whose work, "Hints on Vegetable and Fruit Farming," is so well known. Both these gentlemen reside in the centre of the Kentish fruit district, and their selections of sorts are worthy of general attention. Mr. Bunyard, in his "Fruit Farming for Profit," classifies Apples, first giving early dessert sorts to sell direct from the tree, and these are Red Juneating, Mr. Gladstone, Devonshire Quarrenden, Duchess of Oldenburg, Kerry Pippin, Summer Golden Pippin or Ingestrie, Worcester Pearmain, Prolific or Colonel Vaughan, Sugar-loaf Pippin, and Red Astrachan. Of culinary Apples, also to be sold direct from the tree, he gives Early Julien, Keswick Codlin, Manx Codlin, Cellini Pippin, Lord Suffield, Old Hawthornden, New Hawthornden, Cox's Pomona, Loddington Seedling, Grenadier, Warner's King, Stirling Castle, Ecklinville Seedling. Dessert Apples for keeping: King of Pippins, Cox's Orange Pippin, Blenheim Pippin, Gascoyne's Scarlet Seedling, Wykon Pippin, Golden Knob, Sturmer Pippin, Court Pendu Plat; and of keeping culinary Apples: Blenheim Pippin, Small's Admirable, Golden Noble, Lord Derby, Queen Caroline, Gloria Mundi, Winter Queening, Dumelow's Seedling, Beauty of Kent, Northern Greening, and Prince Albert.

In addition to most of the foregoing, Mr. Whitehead recommends Ecklinville Seedling, Lady Henniker, Gooseberry Pippin, Early Strawberry, Summer Nonpareil, Ribston Pippin, Margil, American Newtown Pippin, Court of Wick Pippin, Claygate Pearmain, and Mannington's Pearmain. If we were planting extensively for market we should not care to plant many sorts, but should rather plant a few sorts by the dozen or hundred that were certain to afford an early, regular, and abundant supply of fruit. Of Apples we would have whole plantations of such sure croppers as Warner's King, Keswick Codlin, Duchess of Oldenburg, Small's Admirable, Golden Noble, and Cellini Pippin, only planting Cellini extensively in deep rich soil, as it cankers badly in thin soils. Then, too, what a profitable investment would an acre or two of Margil be if dwarf bushes of it on the Paradise stock were planted 10 feet apart. For late-keeping fruit Court Pendu Plat, Dumelow's Seedling, and Gooseberry should have preference. Court Pendu Plat starts into growth so late in spring that its blossom escapes damage from late frost. The fruit of Gooseberry keeps good longer than any other Apple, which property gives it an especial value.

Of other fruit profitable enough to grow extensively take Rivers' Early Prolific Plum, Cluster Damson, Prince of Wales Plum, Beurré Clairgeau and Williams' Bon Chrétien Pears, Prince of Wales Raspberry, Warrington Gooseberry, Black Naples Currant, Raby Castle Red Currant. The six sorts of Goosberries highly recommended by Mr. Bunyard are Whitesmith, Early Sulphur, Warrington, Rifleman, Crown Bob, and Lancashire Lad. The fact of this selection having been made from 150 sorts adds to its value.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Earliest House.*—The trees started at the commencement of December will now be in flower, and artificial impregnation must have daily attention. The camel-hair brush should be passed over flowers that have ripe pollen about noon each day, a steady circulation of air being secured by opening the ventilators in front of the pipes, which should be sufficiently heated to raise the temperature to 65° at midday, and 5° to 10° more may be allowed from sun heat. Avoid syringing the trees whilst they are in blossom, but maintain a genial condition of the atmosphere by damping the walls, paths, borders and stems

of the trees in the morning and afternoon of fine days with tepid water. The night temperature should be kept at from 50° to 55° when the weather is mild, but on cold nights allow the temperature to fall 5°. Look well to the outside borders, and guard against sudden chills by keeping the roots covered with some dry non-conducting material. A layer of Oak leaves covered with shutters a foot thick answers well.

*Second House.*—The trees that are to afford ripe fruit early in June have been started, and their buds are swelling fast. Syringe them twice a day, always early enough to allow the trees to become fairly dry before night. Keep the temperature 40° to 45° at night, and 50° in the day by artificial means, advancing 10° to 15° with sun heat. Ventilate from 55°. See that the borders are in a proper condition as to moisture, and if dry afford a thorough supply of water. When the blossoms show colour, and the anthers are clear of the petals, discontinue syringing, but secure a genial condition of the atmosphere by damping all other available surfaces two or three times a day according to the weather.

*Succession Houses.*—Keep these cool and airy, and if the blossoms are likely to become too forward a little shading will retard their expansion—a double thickness of herring or pilchard nets drawn over the roof breaking the force of the sun considerably. The buds are in most cases very forward, and as the sap is more or less active and evaporation constantly taking place, the condition of the border being ascertained, a good soaking should be given if needed so as to insure thorough moisture through to the drainage. It is well not to allow the blossom buds to be subjected to very severe frost after they begin swelling, therefore turn on the heat in very severe weather so as to prevent the temperature becoming very low.

*Late Houses.*—Finish all pruning and cleaning at once, for though Peaches may be pruned from the fall of the leaf up to the blossoming period, many advantages attend the performance of the work before the buds begin to swell. One of the most important is the fact that the young wood may be washed twice or thrice with a much stronger insecticide without fear of injury than when the sap is moving. Ventilate fully, except when frost prevails, and see that the trees have sufficient water at the roots.

*Fumigation.*—A very important operation in the management of forced Peaches is fumigation to destroy aphides, but more particularly through the early stages. We therefore advise that it be made a standing rule to fumigate every house thoroughly just before the blossoms open, and to avoid the introduction of all plants that are not free from aphides. In fumigating after the blossom is expanded great risk is incurred of injuring it, and the foliage also later on is very easily injured by tobacco smoke, consequently it needs to be done at all times with care and judgment, or irreparable injury may be inflicted. It is always safer to fumigate on two or three consecutive evenings moderately than risk fatal results. The foliage should in all cases be dry and the tobacco paper or rag kept from flaring.

**STRAWBERRIES IN POTS.**—Those introduced early in December are now starting; the flower scapes are pushing simultaneously with the young leaves, which is an indication that the crowns have been well ripened, and gives hope of a good crop, inasmuch as there is no loss of vigour in the formation of leaves preceding the development of the flower spike. Advantage should be taken of every favourable opportunity to ventilate, as with growth progressing ventilation becomes a matter of the greatest importance to keep the plants sturdy and insure a strong bloom. The plants should be closely scrutinised for aphides before flowering commences, and if there be any trace of the pest take prompt measures to eradicate it before the flowers expand. Damp the walls and paths in the morning and early in the afternoon, with a little ventilation at the early syringing, the temperature being kept at from 50° to 55° artificially, with an advance of 10° to 15° from sun heat. On bright days the plants as well as the paths should be syringed, as absorption and evaporation will take place much more rapidly, and the atmosphere will become sufficiently dry before dark. Close early so as to raise the temperature to 70° or 75° from sun heat. Allow the temperature to fall to 50° at night, but 5° higher if the weather be mild. Examine the plants daily, giving water if necessary.

#### PLANT HOUSES.

*Trellises.*—Where new or larger trellises are required upon which to train Allamandas, Clerodendrons, and other plants of similar growth, they should be prepared at once, as there is more time now for such operations than will be the case presently. It is a mistake to leave the making of trellises until the plants are ready for potting. Trellises should be thoroughly cleaned and painted annually. Plants are frequently attacked by insects early in the season through the employment of dirty trellises.

*Stakes.*—As opportunity offers, stakes that are not in use should be sorted and tied in bundles according to their size. When deal stakes have been employed for one season they are generally decayed at the base. These may be shortened and pointed ready for use; they will do for plants of dwarf growth as well as new ones. When this has been done it can quickly be estimated how many of the larger sizes are required. These should be made or purchased as early as possible, and painted ready for use. Work of this description can be done in the morning and again in the afternoon at this season of the year. We have found where labour is an object that it is cheaper to buy stakes—that is, all over 2 feet in length, than to make them; these only require painting green to render them neat. All small stakes that we require are made from stout bamboo canes, which are cut into various lengths and then split according to the strength required. These can afterwards be made shapely with but little labour, and are very durable. For Hyacinths, Achimenes, and many other similar

plants these stakes are the most desirable, because they can be made very slender, so that they are scarcely noticeable.

**Labels.**—Good quantities of these in various sizes can be made where required, but they are now so cheap that we have discontinued making them, for we have plenty of other work for all outdoor hands when the weather drives them inside. But where outdoor labour is plentiful and the men are not required for other work during bad weather, they may be profitably employed in this.

**Baskets.**—Where *Nepenthes* and *Orchids* are grown in square baskets made of teak or other wood, new ones may be prepared, for they will soon be wanted. Baskets in which *Ferns*, *Achimenes*, and other plants are to be grown should be thoroughly cleaned and painted. The best and easiest manner of cleaning baskets is to place them for a short time in a copper of boiling water, then paint them thoroughly after they are dry. Wash all pots and pans as they become empty.

**Crocks.**—When employed for the drainage of plants in pots, crocks should be perfectly clean, for this is equally as important as using clean pots. They should be washed and then broken ready for use. After a good heap has been broken they may be passed through different sized sieves, and each size stored by themselves.

**Sphagnum Moss.**—Sort this in readiness for potting. All coarse portions should be reserved for placing over the drainage; reserve the best for *Orchids*. The largest and finest green heads may be selected and placed in pans; these can be kept perfectly fresh in a cool house if watered occasionally. The remainder should have boiling water poured over it to destroy insects.

## THE BEE-KEEPER.

### NOTES ON BEES.

#### THE WEATHER.

ON the day before Christmas the bees were working upon the *Arabis*, with a temperature of 50°, continuing mild up till Tuesday, when there was a heavy fall of snow, at a temperature of 20°, but it gave way to a rapid thaw on the following day. By Thursday the temperature had risen to 50°, and the bees were out in fine style, the day having the appearance of spring. The New Year was ushered in with a similar mildness, but accompanied with wind and rain, bees still seeking an outing. With the frequent airings they have had all danger to abdominal distension may be said to be past for a season. The recent heavy snow has not, however, been favourable to the apiary.

#### HEALTH OF BEES.

All my bees appear healthy, with no perceptible difference in number to what they were at the end of September. There are very few dead bees to be seen, if I except an imported Syrian stock, and I should say of it that it has turned out at least 500 dead bees during December. I have one pure Carniolian located in a deep compound frame hive; but it has not yet shown either a dead bee or a living one at the entrance since October. I examined its floor to-day (the 2nd January), clearing away the debris deposited on the sliding bottom of the ventilating floor, and discovered from their cheerful hum that all was well. This hive has eight frames 17 inches deep by 12½ inches inside measure, and the bees are in the highest state of health, as, indeed, are all similar hives with me.

#### EFFECTS OF CANDY.

Since the memorable successive three bad years about 1860, when candy was used by me for the purpose of keeping the bees alive during summer, I have almost discontinued its use, because I found it wasteful and against the prosperity of the hive when compared with good sugar syrup. One hive I have under my care, during the past month has had nothing but candy for its food. It seems to be surviving on it, and a novice might say doing well, but I observe that unless the bees get an airing frequently they soon get surcharged with water, and with a protracted and severe winter would not exist long. I have therefore come to the conclusion that to feed bees wholly with candy during winter would be simply courting defeat. Novelties may amuse for a time, but will in the end, as of late, compel bee-keepers to return to the old and more rational system of apiculture. When once plans to induce moisture inside hives for breeding purposes are aban-

doned bee-keepers will then find themselves on the way to a better system of bee-keeping.

#### ANSWERING QUERIES.

A great many persons desiring information on apiculture seem to prefer writing me direct. I am willing to answer such letters, but there are other considerations. By answering queries privately it takes away the interest and information from the readers of this Journal. Therefore, in the future, all queries with reply of general interest will be sent to the Editor of this Journal for publication.

#### RECORDING EXPERIENCE.

To make the bee columns of this Journal more instructive, it is desirable that all bee-keeping readers should send their experience in matters of interest, whether it be that of success or failure, stating briefly under what conditions either resulted, together with any supposition the bee-keeper may have as to the cause. By bringing isolated cases together, and examining them collectively, a better knowledge of facts will be arrived at than when single cases only are brought to view.

#### SURPLUS QUEENS.

During the spring months there are always some queenless hives, as well as some bee-keepers having one or more surplus queens which they can well spare, and which would be a great boon to those having queenless hives. I think bee-keepers would feel grateful if the Editor would give a cheap advertisement to those in want of or who had queens to spare (not being tilters) up till May. The advertisement need not be more than name and address, with number of queens wanted or for sale.

#### HONEY PRESSER.

These I have no doubt will be in great request if the Heather harvest is a large one, as by it only can Heather honey be taken satisfactorily from the comb. I have a number of letters of inquiry about these pressers, based upon a reply in the *British Bee Journal* for October 15th, 1885. It says "Young's honey presser is like Mr. Thomson's," which is not the case. The honey presser I have explained and recommended differs greatly from Mr. Young's. Therefore I am not responsible for any mishap with these pressers, nor can I explain the working of any other than the Lanarkshire one.—A LANARKSHIRE BEE KEEPER.

#### DRIVING BEES.

THIS most necessary operation has often caused no little trouble to bee-keepers who, in attempting to drive their bees from one hive to another, have signally failed in the attempt. A most amusing account was given of such a failure in the *Cottage Gardener* many years ago, in which is a vivid description of frantic exertion on the part of a certain bee-keeper who failed to accomplish his object, for the bees, notwithstanding a continued drumming for nearly an hour, kept to their old home. The difficulty was, however, another day easily surmounted. There are few bee-keepers who cannot call to mind some such an amusing episode. In order, however, as far as possible to remove any difficulty which may have been experienced, and to assist those who in spring will for the first time undertake the operation, it shall be my endeavour to state in detail as clearly as possible the methods, which are two in number, by which bees are now driven into an empty hive.

In the first place we must fully realise that it is by acting upon their fears only that we have gained the mastery over bees. It is the knowledge of how to work upon these fears which is indeed the key which has unlocked their treasury. If, then, we have a stock in a straw skep which we desire to drive either for forming an artificial swarm or for clearing the combs preparatory to breaking up the stock, the plan of action is the same, except that in the former case two-thirds of the bees with the queen are taken, and in the latter every bee which can be induced to leave the hive.

The best time for driving is the middle of a fine warm sunny day, although any hour in daylight will do almost equally well. Before in any way moving the hive or disturbing the bees a few puffs of smoke must be injected into the hive, and until by their changed hum it is ascertained that the bees are gorged with honey, and so in high good humour, nothing should be done. When, however, the operator is satisfied upon this point, the stock with its floorboard should be moved to some convenient spot a little distance from the apiary, where the

driving can be performed without getting the rest of the stocks in a state of commotion. On the stand from which the hive to be driven has been removed an empty hive must be placed if the bees are working, to retain such of them as, returning from the fields and finding their home gone, might enter other stocks and cause the death of their queens. After the driving is over these few bees may be joined to the rest of the swarm, and so no life need be lost. The stock must then be carefully loosened from its floorboard and very gently turned upside down, and during this movement the combs must be kept endwise, for if moved other than the way they hang the fastenings at the side of the hive may give way and cause the comb to fall.

All is now prepared for the adoption of whichever system of driving it is desired to use, and these are "close driving" and "open driving," the latter of which is now most generally practised, as the bees can be watched, and if the operator is sharp-eyed the queen picked out as they rush into the upper hive. If, however, close driving is preferred, a hive of the size of the upturned stock must be placed upon it, and a cloth tied round the junction to keep in the bees. If, again, open driving is practised, the upper hive touches the lower at one point only, and this point must be the place to which the combs run. The junction must be secured by a skewer passing through both hives at this junction, and by two iron rods 9 inches long with projecting blades at either end at right angles to the rod some 2 inches in length, and these rods, one on each side of the hive, should have one end of each stuck into the upper hive and one end of each into the lower, and the upper hive can thus be so securely fastened in any position which is convenient as to withstand the shaking caused by drumming. The top hive, it has been said, may be placed at any angle to the other, but possibly a right angle is as suitable a one as it is convenient. In drumming the operator must stand with his back to the strongest light at the opposite end of the combs to the junction of the hives. The object is to cause the bees at this junction to run from one hive to another. The procedure in either system is now the same. Everything being thus prepared, a constant ceaseless drumming must be maintained on the bottom hive, and this drumming must not cease and must be as heavy as possible without endangering the safety of the combs. In the course of a few minutes a general movement will be perceived, and in quarter of an hour but very few bees will remain in the stock, and these, if amounting only to a score or so, may well be left, as all attempts to dislodge them are of little avail, so determined are they to cling to their old home. In driving for swarms the drumming will be stopped when a sufficiency of bees are seen in the upper hive. The bees are now out of their hive at the mercy of the bee-keeper, who can use them for any purpose which seems likely to be of advantage to him.

Nothing has, however, been said of the difficulty which has often been experienced in driving certain hives. There are several reasons which may account for the impossibility of getting bees to leave their hive at certain times, for the queen may be old and feeble, unable to climb into the upper hive, or she may get into some snug corner where the vibration has less effect than in other parts of the hive. The drumming may have stopped while a rest was taken, or it may not have been severe enough; or if there are no sticks in the hive to which the combs are attached the combs may have shut together like the leaves of a book and prevented the exodus. Any of these causes may prevent success, which, however, will surely follow a future attempt; but in very cold weather bees often absolutely refuse to leave the comb unless means are taken to persuade them by putting them into a warm room for a few hours and feeding them, when they can easily be driven. Any man can drive who will make the attempt, but in this, as in other things, perseverance is necessary and judgment; and if these two essentials are made use of success is assured.—FELIX.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Eucharis Roots Destroyed (J. F. G.).**—The bulbs are attacked by the destructive mite that is not by any means easy to eradicate, still we have seen bulbs quite as much injured as those you have sent that were cleansed and afterwards rooted freely, healthy plants resulting, and now producing flowers. Remove all the injured roots and scaly matter from both the base and neck of the bulbs, then wash them thoroughly in a solution made by dissolving 2 ozs. of softsoap with a lump of soda as large as a nutmeg in a gallon of soft boiling water, stirring in briskly while still hot a small wineglassful of common petroleum, such as is burned in lamps. When this has cooled somewhat, but is still as hot as the hand can be borne in it for a moment or two, dip the bulbs in it and rub the solution into every fissure with a soft brush. This mixture will destroy all the mites that are reached. Place the bulbs in small clean well-drained pots of rather sandy turfy loam, embedding them in, and surrounding with crushed charcoal, plunging the pots in bottom heat if convenient; then if the soil is kept moderately moist, but not distinctly wet, fresh roots will in all probability be emitted. A little soot and bruised charcoal mixed with the turf used will be an advantage, as much as would fill a dessert spoon being sufficient of the former for a 5-inch pot; charcoal may be safely used more freely.

**Pruning Gooseberries (Pershore).**—Whinham's Industry Gooseberry has been illustrated in this Journal, and testimony published of its productiveness. You are not likely to spoil your newly planted trees by rather close pruning, provided you cut to prominent buds on the young wood, or that formed last year (1885), selecting those buds that point in the direction you wish future growths to extend. First thin out the growths if numerous, making cuttings of those removed, and leaving those retained 6 inches asunder. These may be shortened to 3 or 4 inches, the parts removed if long enough being inserted as cuttings. When a choice is afforded we prefer cuttings 15 to 18 inches long, but have inserted them less than a third of that length, or two joints within the soil, and one or two above it, the buds being removed from the portion inserted if suckers were not desired for future cuttings. The cuttings should be inserted firmly in sandy soil. The leading growths of established Gooseberry bushes may be left longer than above indicated, and side growths from the main branches may be shortened to within an inch of the base of the young wood both on newly planted and established trees.

**Acacia platyptera (Clifton).**—The above is the name of the plant of which you have enclosed a spray. It may be slightly pruned after flowering so as to prevent a loose or irregular habit of growth. When the plants start growing afterwards they should have the drainage rectified if needed, some of the old soil being removed, and a top-dressing of fresh added, pressing it down firmly. They grow well in sandy loam with a little peat added. Any that need larger pots must be shifted instead and top-dressed, but large shifts and overpotting should be avoided. For a time they should have a very light position in a greenhouse or pit, and towards the middle of summer may be stood in a sunny position outdoors to ripen their growths, taking care that worms cannot enter the pots, and that the roots are not scorched by the heat of the sun. Propagation is readily effected by inserting cuttings of sturdy growths about 4 inches long just when getting a little firm in sand under a bellglass in moderate heat, keeping them moist and shaded, not heavily, till rooted, then exposing them to light and air gradually till they will endure all that can be afforded of both.

**Planting Shrubs (An Old Subscriber).**—We are willing to help you, but feel at a great disadvantage, inasmuch as your plan is not drawn to scale, and you leave us to guess at the width from the flower beds to the path at A B C and D on the plan. We doubt very much if you have nearly sufficient space for either of the Piceas. As the lawn appears narrow we should have thought that narrow columnar shrubs of the Irish Yew type much more suitable, planting them in pairs, one pair in the angles on each side A, so as to not obstruct the flower bed; the next pair in the angles between the oval-shaped and oblong bed; another pair in corresponding portions beyond, and the next pair at C and D on the plan. If you like to send us a plan of the lawn and flower beds drawn to scale so that we can understand the extent of space, repeating your wish, your letter shall have our best attention; we cannot answer your present letter satisfactorily.

**Hyacinth Roots Decayed (C. S.).**—If the roots are in the deplorable condition you represent we know of no other plan for inducing growth than removing the pernicious soil from them and potting in sandy loam with some crushed charcoal for surrounding the bulbs. When bulbs are plunged outside it is easy to throw off heavy rains by thatched hurdles, boards, or shutters; but we suspect the soil employed has been the chief cause of the evil. It must either have contained something injurious or of such a reten-

tive nature as to have been rendered sour by stagnant water. A sandy porous soil should always be used from which water can drain freely. The bulb-farms of Holland are composed mainly of sand, almost a "blowing sand" in hot weather. N.B.—This reply was prepared for insertion last week, and we regret it was accidentally overlooked by the printer, but as you appear to have commenced doing very much what we have suggested we are glad to feel that no serious inconvenience is likely to result by the delay.

**Pears not Ripening (A. L.).**—Many Pears fail to ripen because they are gathered too soon, and then stood in a very light dry place, whereby their juices escape and the fruit becomes dry and remains firm. As you give us no particulars to guide us in forming a judgment in your individual case we are only able to give this general reply. We did not publish the report to which you refer, because it was a distinct and most effective advertisement of the products of a firm who do not advertise in our pages; we do not, however, suppose for a moment that you were animated with other than a worthy motive in sending the report.

**Lapageria Unhealthy (Mitchellean).**—There are two main reasons why these plants are often in an unsatisfactory state in pots:—1, Close soil not sufficiently drained, and hence sour. 2, Pots so densely crowded with roots that the plants do not receive adequate support. Lapagerias usually grow best planted out in a bed at least 18 inches deep, the bottom 6 inches being of drainage, broken clinkers and charcoal being excellent, the remainder springy turfy peat and loam, twice the quantity of the former, with a liberal admixture of charcoal, the whole to be pressed down as firmly as the turfy nature of the compost permits. A bed thus prepared can scarcely be made sour, due provision being made for the free exit of water from the drainage, and when the soil is permeated with roots it is not easy to give too much water; until then water must be given more sparingly, yet the soil should never get anything like dry. If you prefer growing the plant in a pot, prepare the soil similarly. In the event of your plant not having rooted freely, it will be advisable to remove a good part of the old soil, which will be sour, and give fresh as suggested, thinning out and shortening wiry growths to the best buds you can find, syringing the plant twice or thrice a day according to the weather, to prevent excessive evaporation from the leaves, and so assist the emission of fresh healthy roots, which alone can invigorate the plants. We know of Lapagerias that grow luxuriantly and flower profusely on the north side of greenhouses.

**Planting and Pruning Apricot Tree (J. W.).**—We presume your tree is young. If it is well rooted—that is, has a good number of fibrous roots, we should not shorten the branches to any great extent. In planting cut off all jagged roots and bruised portions and plant in a mixture of fresh loam, lime rubbish, and wood ashes, laying the roots out straight, separating them, and packing the soil rather firmly round them, covering about 5 inches deep and spreading littery manure over the surface and for a foot or more beyond the extension of the roots. If the branches are numerous remove some of the weaker entirely, so that the others can be disposed 8 or 9 inches apart, and if there is a foot between them at a distance of 3 feet from the stem all the better. Assuming roots are plentiful, we should only remove the unripe ends of the branches, say a length of 6 inches, more or less according to their condition and with due regard to the symmetry of the tree, cutting from below and starting the undercut above what is to be the terminal bud, not below it, bringing the knife out above, as is frequently done. The lower branches of a tree should as far as possible be in advance—that is, longer than those above them, so that the lower part of the wall may be furnished. There is no difficulty in covering the upper portion. When a branch is disposed to lag behind, it should be trained more or less towards a vertical position, those fully too strong being correspondingly depressed. When luxuriant shoots push from the centre of a tree and threaten to draw the sap from the weaker growths below, the tips may be taken from the strong shoots when 6 inches long, and the secondary growths that will push will quite equal in strength the first growths on the lower branches. Apricots trained thinly and a good balance of growths maintained in summer, the roots encouraged to extend in rather firm and not over-rich soil near the surface, produce short-jointed wood that matures and becomes fruitful in character, and no more shortening of the branches is then required in the winter than may be advisable for forming a well-balanced fruitful tree. Do not secure the branches tightly to the wall on planting, as the soil may settle somewhat and drag the roots downwards if the branches are immovable. The Hemskerk is a variety of the Moorpark, and one of the most useful Apricots you can grow.

**Pruning Fruit Trees (W. A. K.).**—The condition of the roots is an important factor in determining the extent to which the branches of recently planted trees should be shortened. The more plentiful the roots are, especially those of a fibrous nature, the longer the branches may be left, and the more sparse the roots the closer should be the pruning of the shoots. See our reply to "J. W." on pruning and planting Apricot trees. You will perhaps not err by removing about one-fourth the length of the branches of your trained Plum and Cherry trees, but the roots must be your guide. The pyramid trees should be thinned out if the growths are numerous, the main branches being from 9 inches to a foot apart, any side growths on them shortened to about two buds, the terminals being left 8 or 9 inches long according to their strength and the symmetry of the trees. Stone fruits are best attended to by disbudding and pinching the growths in summer so as to reduce the necessity of winter pruning to a minimum. Morello Cherries when established require scarcely any pruning in the winter, as the wood if trained thinly in the summer in order to become matured bears throughout its length like that of Peaches; it is often advisable, however, to both thin out and shorten the shoots of newly planted trees to insure a good growth the first season, then disbudding to prevent overcrowding is the most important point in management. The "Garden Manual," published at this office, price 1s. 6d., post free 1s. 9d., contains practical instructions on the management of trees.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (J. L.)—The Grapes were more or less broken in transit. They appear to be well kept examples of Foster's Seedling. (A. Brook).—The Pear is Vicar of Winkfield. The Apple we do not recognise. (H. H. Craw).—Nos. 1 and

2 are quite correct. No. 3 is not Old Nonpareil. We believe it to be Ked-dleston Pippin. (J. Beadle).—1, Flower of Kent; 2, Wormsley Pippin; 3, Pomme de Neige; 4, Alfriston; 6, Calville Blanche. (Old Subscriber).—1, Ne Plus Meuris; 2, Comte de Lamy; 3, Not known; 4, Josephine de Malines. (J. A.).—Mère de Ménage. We have boxes of fruit—indeed, we always have—with no senders' names enclosed, and the specimens cannot consequently be named.

### COVENT GARDEN MARKET.—JANUARY 13TH.

### AGRICULTURAL PROGRESS.

WITH a full recognition of the absolute necessity of close attention to economy in every detail of farming comes a natural longing for efficiency in the implements and machinery of the farm. In very few of these do we yet find absolute perfection, but progress is being made, in many instances with singular rapidity, and we may certainly look with satisfaction from the sickle, flail, plough, wooden roller, and heavy tumbrils of our forefathers to the implements of our own day. Yet the change from unwieldy old tools to the lighter yet more useful modern ones has been, and in point of fact is still, marvellously slow. Many a man still clings persistently to old tools, and old half-worn farming plant is still in much demand, as the brisk competition by buyers at Michaelmas auction sales shows plainly. The

reason for this is not far to seek. Old implements are as dear to the farmer as old customs, but it is undoubtedly the high prices of new implements and machinery that militate against anything like a brisk sale. When will middlemen come to see that it is as much to the advantage of the seller as the buyer to keep down prices? The large profits made upon penny postage, cheap telegrams, railway travelling, and cheap literature, all point to the general advantage of the nimble ninepence over the slow shilling. The simile may appear somewhat far-fetched, but it is nevertheless true and forcible enough. Close inquiry into cost of production, and the price paid by the farmer after the different profits have been added to it, show plainly how heavy is the tax he is made to pay to the middlemen. There is a case in point. A few months ago we required a new farm cart for one of our farms, and we wrote for prices to an implement maker at a town only a few miles distant from the farm. By return of post the keen tradesman sent us a bulky packet of his illustrated circulars, an illustrated catalogue—the time of trains arriving and leaving the town, an offer to meet us at the railway station with a conveyance, and a somewhat premature expression of his gratification at having secured our custom. Now, the price list showed us that the sort of cart we required would cost from £17 to £29, so we went to the village wheelwright, whose offer to make a strong useful farm cart for £11 was at once accepted, and the cart made for that moderate sum is one of the best we have. Plain, strong, yet not too heavy, without any pretentious and useless embellishments, it compares favourably with any of the costly patent carts for which we have to pay so dear. Depend upon it that with low prices and good workmanship there would be a much larger sale, not only of carts, but of all other useful farming implements.

Simplicity and efficiency are generally found in pleasing combination in the best implements and machinery. Elaborate combinations have almost invariably to make way for simple forms. That triumph of ingenuity and skill, Hornsby's sheaf-binding reaper, gains in utility with greater simplicity. About half the parts of the knotter have been discarded. Steel has largely taken the place of iron, affording lightness with strength, and several other improvements have been made. Very pleasant and instructive is the sight of one of these wonderful machines at work. A degree of speed, neatness, and finish is attained altogether superior to anything we have met with in the harvest field. Wise indeed in their generation were the farmers who secured "a Hornsby" for last harvest. We were favoured with glorious weather during the earlier weeks of harvest, and with the aid of self binding reapers the work was got through with in half the usual time. Very little Barley was washed or discoloured, all being safely housed before the long spell of wet weather set in, and which spoilt so much Barley. The result is significant. Barley saved before the rain has commanded 40s. a quarter, while Barley discoloured by rain has been sold for half that sum. Surely the lesson is sufficiently plain to be grasped by every farmer. We attend a corn market where there has for the last two months been an average weekly sale of 5000 quarters of Barley, and while the range of prices has been considerable, yet every sample has undoubtedly been treated on its merits, some ranging a little higher or lower perhaps, according to the keenness of buyer and seller. Careful threshing and thorough dressing are also highly important factors in the production of a good sample of corn. There is much difference in the work of threshing machines as well as of corn-dressers, and we ought not to rest satisfied with anything short of the best work. Messrs. Rainforth's flat adjustable corn screen is one of the best we have seen, and the Judges of implements at the Preston meeting of the Royal Agricultural Society marked their sense of its high merit by the award of a silver medal. Thorough separation of head and tail corn and of the seeds of weeds is what we require, and this is the test to apply to

a corn-dresser, which ought always to be purchased subject to such a trial.

We were glad to see elevators brought into more general use last season, both for stacking hay and corn. Considerable economy of labour is effected by means of an elevator, which does the heavy work of pitching on to a stack expeditiously and well, two or three men less being required. Brisk prompt action is all-important during harvest, and whatever contributes to it is highly valuable. Thoughtful discussion of such matters now should enable us to arrange our plans for the coming season of activity both wisely and well.

#### WORK ON THE HOME FARM.

Much good work is being done in cutting down timber in hedgerows, enclosing arable land, in thinning timber in woods, in park clumps and belts, and in tree planting. This part of the home farmer's duties is worthy of especial attention, and a man must have special training for it. The planting and arrangement of trees for effect as well as for profit may be said to fall within the province of the landscape gardener, but those who have the management of landed estates find their services more highly valued and more profitable to themselves if they are really skilful in the management and arrangement of trees. Although owners of such property may not have practical knowledge, yet they generally possess refined taste, which enables them to recognise and appreciate skilful work when they see it. Fondness for trees ought never to be allowed to interfere with judicious thinning. By all means plant thickly at first, but do take care to thin plantations before growth becomes so much crowded as to affect the health or symmetrical growth of the permanent trees. Only a day or two previous to writing this note we were asked to inspect some neglected belts and clumps in a park, and we found that in some of them the trees had suffered so much from overcrowding that fine timber or ornamental growth was now an impossibility. Every tree in the interior was so drawn up and attenuated as to be quite spoilt. Some of the outer ones were more vigorous, but the branches' growth was one-sided and totally deficient of symmetry, and our advice was either to leave the clumps alone or to destroy and replant them. Our own home practice this season consists in opening out many pleasant views and fine trees in park scenery; in giving an air of lightness and expanse to the surroundings of the mansion by so thinning and opening belts near the dressed grounds as to bring some fine trees in the park into sight from the garden, and some views of distant scenery. Young plantations have been thinned sufficiently to let in air and light to the permanent trees, of which there are many thousands, consisting of thriving young Cedars, Scotch and Austrian Pines, Larch, Wellingtonias, White Spruce, Piceas, and a tasteful mixture of such deciduous trees as Limes, Sycamores, Maples, Oaks, Beeches, Poplars, Chestnuts, and Ash. The planting of underwood is also being done, Spanish Chestnut being planted in all sound well-drained soil, Ash in deep heavy soil, and Alder in low-lying damp places. Where there is a demand for hoop wood for cement casks Hazel proves profitable underwood, and it grows freely in deep or shallow soil that is not waterlogged. The most unprofitable underwood is Oak-scrub, and it is for this reason that we always insist upon having all Oak trees in woods grubbed up by the roots and not sawn off.

#### OUR LETTER BOX.

**Drying Bacon (J. D.).**—We should not venture to dry the bacon in a stovehole in which coke is burned on account of the sulphurous fumes emitted, and which would be absorbed by the flitches, and impart a flavour that would be the reverse of palatable.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

3rd.—Fine day, but wet night.  
 4th.—Warm and wet all day, clear cool night.  
 5th.—Fine, bright, and cold.  
 6th.—Heavy snow, 4½ inches deep at 9 A.M., 5½ inches at 10 A.M., 7 inches at 11 A.M., and 9 inches at noon; fine bright afternoon.  
 7th.—Fine, bright, and freezing hard.  
 8th.—Nearly an inch more snow in the night, followed by a thaw; fine bright day.  
 9th.—Gloriously fine and bright; solo halo in morning.  
 Temperature rather below the average, and a heavy fall of snow on Wednesday, 6th.  
 —G. J. SYMONS.

26	TU	
27	W	Society of Arts at 8 P.M.

### LIME FOR VINE BORDERS.

**I**T is a very general practice in gardening establishments to remove the surface soil or manure from the borders after pruning the Vines or previous to starting them into growth, and to give a fresh supply. These annual top-dressings are often composed of fibry loam and decayed manure with a small per-centage of bones, wood ashes, or soot. A compost of this description is preferred by many to a heavy dressing of cow or other farmyard manure, either in a fresh or half-decayed state. The latter is perhaps more generally used for the majority of Vine borders, for it can often be had for this purpose when fibry loam cannot. Where appearances have to be considered and manure on the surface of the border would be objected to, it is readily concealed by a thin coating of loam. For some years I used the above compost in preference to all manure, and mulched the surface of the border afterwards with the manure from spent Mushroom and hotbeds. The latter was not done so much to provide food for the Vines as to keep the surface of the border moist during bright weather, for in this condition the roots work with great activity near the surface. When the roots are near the surface to commence with, and the border is top-dressed and mulched afterwards with some moisture-holding material, this is certain to become full of active feeders every season. The opposite is the case when the surface of the border is dry, for the roots go downwards.

There can be no doubt that in some instances a heavy dressing of manure will prove beneficial. The Vine food that it may be most necessary to supply annually, or at certain intervals, to maintain the border in a fertile state, depends chiefly upon the amount of suitable food the staple soil of the border contains, and how long it has been made. If we suppose that the compost used at the commencement contained all that is essential for the growth of the Vine and perfecting the fruit, it will at some time require renewing. The formation of the borders and the enormous quantity of water supplied to them during a season or two is sufficient to wash out of the soil much food of the utmost value for the proper support of the Vines. Even if they took nothing out of the border it would become practically unfertile in less time than many really suppose through the cause indicated. Under such circumstances it becomes necessary to add annually or at certain periods fresh supplies of food or the crops would fail.

Experience and observation have convinced me that more borders are deficient in calcareous matter than anything else requisite for the Vine. There may be a few examples to the contrary. I know of one instance where calcareous matter was too abundant in the soil used for the Vines, and they failed to give satisfaction until a large per-centage of fresh soil was imported from a distance, and ever since they have been all that could be desired. In many cases the borders are made of loam that is practically destitute of lime, and thousands of cultivators have no other chance than to use it. This deficiency may be provided against, and fre-

quently is, by adding lime or lime rubbish to the compost when the border is first made. The quantity added may prove sufficient for a few years, and the Vines give every satisfaction, but afterwards the fruit fails to stone or colour and come up to the standard required. The usual top-dressings of soil or manure may be supplied every season, but these prove of no avail—in fact, heavy dressings of manure soon prove detrimental if the border has become deficient of lime, which is of the utmost importance to the production of fine well-coloured fruit.

Mistakes are often made through the want of knowledge as to whether the soil to be used for the borders and top-dressing contains lime or not. Frequently under such circumstances an insufficient quantity of lime is given, which perhaps for years results in the Vines not giving the cultivator in charge the satisfaction he desires. Some years ago the soil of an old kitchen garden that had been heavily manured failed to grow Cabbage or anything else, and this was rendered thoroughly fertile by applying a heavy dressing of fresh lime. The improvement of the soil was so marked that I was tempted to try the effect of lime on Vines by applying it to the border in which they were growing and being forced. The Grapes had advanced to the colouring stage, when suddenly they came to a standstill. The lime was mixed with water in a tank outside the house, and then poured upon the border and washed in with tepid water. The effect was soon observed, and the Grapes coloured fairly well, but all hopes of their doing so had been given up. In autumn several barrowfuls of lime were worked into the border, and little trouble was experienced in colouring the Grapes afterwards.

Previous to this we had commenced making some new borders on the "piece-meal" system, but added to the loam used only a very small quantity of lime, which experience has since taught us was insufficient. Much more lime than many suppose must be added to soil for the benefit of Vines if they are to give the greatest satisfaction. When the loam used is almost destitute naturally of this ingredient no less than 12 per cent. should be added when the border is first formed, or in this proportion as each part of the border is made. When this is incorporated with the soil before it is placed in the border it will appear very white, and almost lead beginners to think that they are employing too much. But this will not be the case if the loam is in the condition indicated, and contains practically no lime. After the whole of the border has been completed, say for two years, no less than 10 per cent. should be added to the compost advised above for top-dressing every second year. We prefer adding to the quantity of compost used about half the quantity annually, and have found this practice to succeed admirably. When mixing the compost the manure, as well as the other ingredients, are thoroughly incorporated before they are applied to the border. The lime should be perfectly fresh, and reduced to powder by pouring water upon it. The heap of soil should then be turned over and left under cover in a shed for a day or two if possible, and the moisture of the loam and manure reduces to powder any lumps of lime that may not have been thoroughly reduced by the first operation. By this means the lime is thoroughly mixed with the soil before it is placed on the surface of the border. When the border is drained liberally and water given frequently more lime is washed out of the soil than would be the case with less frequent applications of water and less perfect drainage.

There must be thousands of Vine borders composed of soil in which lime did not naturally exist, and if not added when the border was made are at the present time short of this important substance. The greater part of many borders—that is, as far as the staple soil of the border is concerned—within my own knowledge has been made with turf cut from land with a sandstone formation. It is perfectly clear from the luxuriant growth of Rhododendrons and other

non-lime-loving plants that the soil from such formations contains only a very small per-centage of lime, and in many instances practically none. The growth of these plants—that is, when in the native soil, will prove an invaluable guide by which the soil to be used may be judged. But beginners must not be mistaken when practising on what is technically called the “outcrop” of the layer or stratum of sandstone, for the soil may differ greatly only 100 yards away. Under these circumstances the growth of the plants referred to might be totally altered, and therefore judgment and forethought are needed in selecting soil, and adding lime to it for Vines. In cases where borders have been made with soil from a sandstone formation, and the Grapes are not colouring well, or the Vines doing satisfactorily in other respects, and the quantity of lime given them has been small, they might be materially improved by a liberal dressing for a season or two, the dressings of manure being dispensed with for that time.—WM. BARDNEY.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 10.)

### SELECTION OF VARIETIES FOR VARIOUS PURPOSES.

In giving a selection of varieties for various purposes I have endeavoured to name those which are distinct. They are all well adapted for growing in the style in which they are classed. There are perhaps a few newer varieties which will take a leading position when they become better known, but not having had an opportunity of testing them I prefer to leave them out through fear of causing disappointment. For those growers who cannot have all the varieties named in each section I have placed the varieties first which I consider the best; therefore a reduced selection can be made according to the number required. As these varieties are so well known the full descriptions and colours of each can be had from any of the many excellent catalogues now published.

#### FORTY-EIGHT JAPANESE VARIETIES FOR CUT BLOOMS.

Mdme. C. Audiguier	P. ter the Great
Belle Paule	Elaine
Fair Maid of Guernsey	Soleil Levant
Meg Merrilees	Album plenum
Jeanne Delaux	Japonaise
Baron de Prailly	Mr. John Laing
Criterion	Mdme. Bertie Rendatler
Val d'Andorre	Mdme. de Sevin
Boule d'Or	Balmoreau
Mdme. Lacroix	Flamme de Punch
Margaret Marrouch	Mons. Tarin
Comte de Germiny	Grandiflorum
Duchess of Albany (Jackson)	Fanny Bouchardat
M. Astorg	M. Delaux
Mrs. Mahood	Mdme. Deveille
M. Ardene	Sarnia
Sceptre Toulousain	Bouquet Fait
Golden Dragon	Dr. Macary
Fernand Feral	Red Gauntlet
Hiver Fleuri	Margot
Thunberg	Père Delaux
M. Burnet	Triomphe du Nord
L'Adorable	L'Africaine [George Gordon]
Triomphe de la rue des Châlets	La Nympe

#### TWELVE JAPANESE FOR SPECIMENS.

Bouquet Fait	Comet
Hiver Fleuri	Lady Selborne
L'Africaine	Fair Maid of Guernsey
La Nympe	Album plenum
Peter the Great	Joseph Mahood
Mdme. Bertie Rendatler	Triomphe du Nord

#### FORTY VARIETIES INCURVED FOR CUT BLOOMS.

Lord Alcester	Lady Carey
Empress of India	Sir Stafford Carey
Queen of England	Princess Beatrice
Golden Empress	Cherub
Golden Queen of England	Baron Beust
Alfred Salter	Barbara
Princess of Wales	Nil Desperandum
John Salter	Miss Mary Morgan
Lord Wolseley	White Venus
Prince Alfred	Novelty
Jeanne d'Arc	Beauty
Hero of Stoke Newington	Mr. Brunlees
Jardin des Plantes	Eve
Mrs. Heale	Nonpareil
Princess of Teck	Bronze Jardin des Plantes
Refulgence	Yellow Perfection
Mrs. Bunn	Pink Venus
Empress Eugénie	Mahel Ward
Mr. W. Shipman	Lady Slade
Lady Hardinge	Prince of Wales

#### TWELVE INCURVED FOR SPECIMENS.

Lord Alcester	Mrs. Sharpe
Empress of India	Mrs. G. Rundle
Queen of England	Mrs. Dixon
Golden Queen of England	George Glenny
Golden Empress	Venus
Prince of Wales	Lord Derby

#### FIFTEEN REFLEXED VARIETIES FOR CUT BLOOMS.

Cullingfordi	Phidias
King of Crimsons	Peach Christine
Golden Christine	Pink Christine
Distinction	Chevalier Damage
Mdme. Madeline Tezier	Felicity
Mrs. Forsyth	Sir Edwin Landseer
Cloth of Gold	Emperor of China
Dr. Sharpe	

#### SIX REFLEXED FOR SPECIMENS.

Dr. Sharpe	Pink Christine
Mrs. Forsyth	King of Crimsons
Peach Christine	Chevalier Damage

#### TWELVE ANEMONE VARIETIES FOR CUT BLOOMS.

Lady Margaret	Empress
Fleur de Marie	Georges Sands
Gluck	Prince of Anemones
Acquisition	Mdme. Goderau
Minnie Chaté	Princess Louise
Mrs. Pethers	Louis Bonamy

#### EIGHT VARIETIES ANEMONE JAPANESE FOR CUT BLOOMS.

Fabian de Mediana	Margaret Villageoise
Mdme. Clos	Souvenir de L'Ardenne
Sœur Dorothee Souille	Mdme. Berthe Pigny
Mdme. Cabrol	Duchess of Edinburgh

#### TWENTY FOUR VARIETIES FOR GROUPING.

Val d'Andorre	George Glenny
Triomphe du Nord	Jeanne Delaux
Mons. Henri Jacotot	Meg Merrilees
Mdme. de Sevin	Elaine
M. Astorg	King of Crimsons
Cullingfordi	Jardin des Plantes
Mdme. Lacroix	Prince Alfred
Bouquet Fait	Mr. Bunn
Princess of Teck	Chevalier Damage
Mdme. C. Audiguier	Simon Delaux
Mrs. G. Rundle	Dr. Macary
Mrs. Dixon	Hero of Stoke Newington

#### TWENTY DECORATIVE VARIETIES.

Lady Selborne	Mdme. Desgrange
Mrs. G. Rundle	Triomphe du Nord
Mrs. Dixon	Simon Delaux
George Glenny	Mons. Mousillac
Mons. H. Jacotot	L'Africaine
Cullingfordi	Margot
James Salter	La Nympe
Flocon de Nieve	Flambeau
King of Crimsons	Dr. Sharpe
Bouquet Fait	Progne

#### FOURTEEN VARIETIES FOR LATE BLOOMING.

Princess of Teck	Miss Maréchaux
Hero of Stoke Newington	Fanny Bouchardat
Meg Merrilees	Ethel
Ceres	Miss Margaret
Grandiflorum	Thunberg
Mrs. C. Carey	Nonpareil
Fair Maid of Guernsey	Lady Carey

#### FIFTEEN VARIETIES OF POMPONS.

Black Douglas	Pygmalion
President	Nellie Rainford
Marabout	Prince of Orange
Toussaint Maurisot	Reine d'Or
La Pureté	Cendrillon
Madame Marthe	Eléonore
Golden Madame Marthe	Rosinante
Lizzie Holmes	

#### TWELVE VARIETIES ANEMONE POMPONS.

Madame Montels	Marguerite de Coi
Queen of Anemones	Perle
Antonius	Sidonie
Mr. Astie	Marie Stuart
Regulus	Zohedie
Calliope	Aglaia

#### SIZES OF EXHIBITION BLOOMS (A GUIDE).

It is difficult for inexperienced growers to know what size to aim at in growing Chrysanthemum blooms for exhibition. They are often in error in judging their own flowers, not having seen really representative specimens of the various kinds. The best of all guides is measuring the flowers, and keeping records of them for comparison in following years. I give the sizes of some of the

blossoms which have been grown at Swanmore Park. The list could be much increased, but will suffice as typical of large, medium, and smaller varieties. Larger measurements could be given, but not consistent with the depth and solidity required, these qualities being absolutely necessary for blossoms to win in good company at the leading exhibitions. Flowers are often measured larger in diameter, particularly in the early season, but they lack depth and solidity; therefore I should warn young beginners to pay more attention to depth than mere width, especially in the incurved section. The first figure following the name in the following list denotes the diameter of the flower in inches, and where a second figure is given that signifies the depth of the bloom. The best way to measure the blossoms when on the plant is to place the left hand under the florets and gently raise them to a horizontal position, then with a rule passed under the size can be determined. In the case of irregular-petalled kinds it is not well to take the extreme outside size, but take a fair average measurement consistent with the depth of the flower. Sometimes one or two florets will have advanced a long way beyond the general quantity, and to measure such would be misleading, as all flowers of the same kind do not have these extra long florets. In considering the depth allowance must be made for the reduction in that part which is made when incurved blossoms are cupped ready for show, to allow of the petals being arranged in proper form, and reduces the flowers in depth considerably, because the weight of the petals without support has a tendency to deepen the blossoms, and when measured in this manner disappointment often occurs when prepared for exhibition. Ours are generally measured when arranged on the stands ready for conveyance to the show.

**JAPANESE.**—M<sup>de</sup>. Audiguier, 7 by 6 inches; Meg Merrilees, 9 inches; Fair Maid of Guernsey, 8½ inches; Comte de Germiny, 6 by 4 inches; Elaine, 6 by 4 inches; Baron de Prailly, 9 inches; Jeanne Delaux, 6 inches; Criterion, 6½ by 4 inches; Boule d'Or, 8 by 5 inches; Marguerite Marrouch, 6½ by 4½ inches; M<sup>lle</sup>. Lacroix, 7½ by 4 inches; Hiver Fleuri, 6 by 4 inches; Peter the Great, 6 by 4 inches; Mons. Tarin, 7½ inches; Thunberg, 7 by 4½ inches; M. Ardene, 7 by 4 inches.

**INCURVED.**—Lord Wolseley, 6 inches; John Salter, 6 inches; Jeanne d'Arc, 5 by 4½; Princess of Wales, 6 by 3 inches; Empress of India, 6 by 4 inches; Queen of England, 6 by 4 inches; Golden Empress, 5½ by 3 inches; Alfred Salter, 6 by 3½ inches; Hero of Stoke Newington, 5 by 4 inches; Princess Teck, 4½ by 2½ inches; Mrs. Bunn, 5 by 3 inches; Refulgence, 5 by 3 inches; Barbara, 4½ inches; Eve, 4½ by 2½ inches; Jardin des Plantes, 5½ inches; Lady Hardinge, 4½ by 2½ inches.

**REFLEXED.**—King of Crimsons, 6 by 4 inches; Golden Christine, 5 by 3 inches; Dr. Sharpe, 5 by 2½ inches; Cloth of Gold, 5 by 2½ inches; Mrs. Forsyth, 4½ by 3½ inches; Pink Christine, 4½ by 3 inches.

**ANEMONE JAPANESE.**—M<sup>de</sup>. Clos, 6½ inches; M<sup>de</sup>. Cabrol, 8 inches; Sœur Dorothee Souille, 6 inches; Fabian de Mediana, 8 inches.

**ANEMONE FLOWERED.**—Acquisition, 6 inches; Fleur de Marie, 5 inches; Mrs. Pethers, 5 inches; Gluck, 4½ inches.

—E. MOLYNEUX.

(To be continued.)

## THE CULTIVATION OF THE LEMON.

I KNOW of few places in this country where the Lemon is grown specially for its fruit. The plants, like the Orange, are generally grown in boxes to ornament the terrace and flower garden during a few months in the summer, and then stored away for the winter in some dark shed or barn where they will be safe from the effects of severe frosts. Plants treated in this way cannot be expected to produce fruit in quantity or of good quality.

The cultivation of the Lemon as a fruit-bearing tree is simple enough to those who possess the means. When properly attended to the plant will yield abundant crops of much larger and finer fruits than the imported ones that are so plentiful in our markets. The fruit can be grown to great perfection in a lean-to vinery or Peach house when planted out and trained on the back wall.

Margam Park, in this county, has been long famed for its large collection of Orange and Lemon trees, some of which are of great antiquity. By far the greatest number of these are grown in large boxes to ornament the terraces and pleasure ground, where they produce flowers in great abundance, which fill the air in the immediate vicinity with their sweet fragrance. Besides those which are grown in boxes, a great many varieties of Oranges and a few Lemon trees are planted out in the border of a long lean-to greenhouse, and trained on the back wall, which they completely cover from top to bottom, and mature heavy crops of fine fruits annually. It was from these trees that Mr. Muir gathered the fine collection of Oranges that obtained the gold medal at the Manchester International Flower Show a few years since. The first time I saw the Lemon trees growing in this way at Margam Park, some ten or eleven years since, I was so pleased with them and the crops they were

bearing, that I resolved to grow some in the same way here. I raised a few Orange plants from seeds the same year for stocks, and when these were sufficiently strong I obtained a few Lemon scions from Mr. Muir, and grafted them. In due time three of the best of these were planted close to the back wall of a lean-to vinery in a compost principally of rich yellow loam, a little leaf mould, and some crushed bones. The plants in a short time covered the wall, and they have been carrying heavy crops of much better fruits than we can get to buy for the last five or six years.

I told one of my young men to count the fruits which are nearly ripe on the three trees to-day. This he did, and informed me there were no fewer than 230. Besides those on the trees I have gathered a great many at different times. During the time the fruits are swelling the trees receive liberal supplies of liquid manure, and they are never allowed to suffer for the want of water at any time. The trees give the back wall a furnished appearance. They do not interfere in any way with the cultivation of the Vines, and their fruits are much prized by the housekeeper at all seasons.—A. PETTIGREW, *Cardiff*.

[Splendid examples of culture accompanied this communication, two sprays each about a foot long, bearing a dozen Lemons, superior to the best we have seen in fruiterers' shops during the week.]

## ON THE STATISTICS OF THE CAPE BULBS.

[Read at a meeting of the Horticultural Club, January 12th, 1886, by J. G. Baker, F.R.S.]

I HAVE not, like Dr. Masters and Professor M. Foster, had any experience worth taking into account in practical gardening; but I hold strongly to the opinion that botanists and gardeners should work together hand in hand, and continually consult one another, and that if they do not do this the work of both will be so much the worse for it. For instance, in these plants we are now considering a description drawn from dried specimens alone is always more or less incomplete and unsatisfactory, and in the Aloiaceæ to draw up any reasonably satisfactory description from dried specimens is altogether out of the question.

Of all the members of the rich Cape flora, which includes the garden Heaths, Pelargonias, and Mesembryanthemums, these bulbs are the plants which possess the greatest horticultural interest, and are at the present time exciting the greatest share of attention. One of the most interesting facts in botanical geography is the way in which the three bulb bearing natural orders, Iridaceæ, Amaryllidaceæ, and Liliaceæ, are concentrated at the southern extremity of the African Continent. All that I can attempt to do in the time we have at command is to lay before you the broad general facts of the case.

In Iridaceæ there are in the whole world fifty-seven genera and 700 species. Of these thirty-two genera and 374 species, or more than half the total number, belong to the Cape; of the genera twenty are endemic, nine found also in tropical Africa, and only three widely dispersed. The large genera, taking them in order of size, are Gladiolus, Moraea, Geissorhiza, Tritonia, Babiana, Hesperantha, Ixia, Romulea, Lapeyrousia. In Amaryllidaceæ there are in the whole world sixty-four genera and 650 species, and of these twenty-one genera and 154 species belong to the Cape; one third of the genera and a quarter of the species. Of the genera, thirteen are endemic, three also found in tropical Africa, and five widely dispersed. The large Cape genera are Hypoxis, Hæmanthus, and Cyrtanthus. In Liliaceæ there are in the world 187 genera and 2100 species; of these there are at the Cape forty-nine genera and 621 species; of the forty-nine genera eighteen are endemic, fifteen found also in tropical Africa, and sixteen widely dispersed. The large Cape genera are Haworthia, Aloe, Gasteria, Asparagus, Ornithogalum, Scilla, Anthericum, Lachenalia, Eriospermum, Bulbine, and Kniphofia.

The area of Africa south of the tropic is about a million square miles. The total area of Cape Colony proper is about a quarter of a million square miles, or about one-two-hundredth part of the whole land area of the world.

In the whole world there are in these three orders 308 genera and 3450 species; and of these 102 genera and 1148 species, or about one-third of the whole number, belong to the Cape. Nearly all the Cape species are endemic; and of the 102 genera, fifty-one, or just one-half, are endemic, twenty seven represented also in tropical Africa, and twenty-four are widely dispersed.

## PHYSICAL GEOGRAPHY AND CLIMATE.

In climate one correlates the idea of bulbs with variability in heat or moisture, or usually in both; a high degree of heat in summer, and the of protection from long periods of drought.

Of the 1100 Cape types about 200 (Bulbine and the four genera of Aloineæ) are succulents, the Asparagaceæ, Anthericeæ, and non bulbous Iridaceæ (such as *Aristea*, *Witsenia*, and *Bobartia*) are about 150 species, leaving a balance of 800 species, in which the rootstock is either a bulb, corm, or tuber.

Turning to the Encyclopædia nearest at hand, I find the physical geography summed up as follows—"The general character of the scenery is rocky and arid; mountains, naked and uncultivated, stony valleys without a tree, a prevailing monotony, absence of shade and verdure and water. For the whole region the coldest months are June and July, the warmest December and January. For Cape Town the annual mean temperature is 62° Fahr., the minimum in the shade being 34°, and the maximum about 100°. All along the south coast there is very little variation in temperature. On Table Mountain, which is nearly 400 feet above sea level, snow lies sometimes for two or three days. At Cape Town the annual rainfall is 24 inches; north-east of Cape Town the annual rainfall sinks to 12 inches. Along the south coast it increases as we travel east and reaches 33 inches at Graham's Town. Parallel with the south coast the land rises in three successive terraces. The highest of these, the great Karoo, has an elevation of 3000 feet, a length from east to west of 300 miles, and of 80 miles from north to south. For nine months of the year the soil is quite bare, and even in the rainy season the vegetation is very scanty. The highest peak of the Graaf Reinet Mountain, the Snivbergen is about 10,000 feet above the sea level, and here the snow lies for three or four months. The highest peak of the eastern range of hills, the Wintterbergh, is 7000 feet above sea level."

#### RELATION OF CAPE FLORA TO THAT OF TROPICAL AFRICA

I should like to say a word about the relationship of the Cape flora to that of tropical Africa. It would seem that just as in Europe there was a glacial epoch, and when a warmer climate set in the cold-loving plants were pushed out to the north mountain tops, so in Africa there has been, since the present vegetable genera were differentiated, an era of universal cold, and the plants that then flowered over the whole continent have been pushed out to the Cape and up to the mountain summits of the intertropical zone. As I previously pointed out, fifty-one genera out of 102 are confined to the Cape, but of characteristically Cape genera in these three orders alone outlying representatives of twenty-seven are found high up amongst the intertropical mountains.

#### FLOWERING SEASON OF SOUTH TEMPERATE TYPES.

In conclusion, as a subject for discussion this evening, what I want to ask you as an assembly of experienced horticulturists is this, How far is it possible by cultivation to change the natural flowering time of these south temperate plants? In the three great floras of the south temperate zone there are probably not less than 25,000 plants, say 25 per cent. of the whole vegetable kingdom. Which are the plants, or if that be too comprehensive a question, which are the types of the natural orders about which we are speaking, for which we can alter the natural flowering season so as to grow them in the open air in the English climate, and which are the types for which we cannot do this? Upon what does the difference depend, and in the case for which it is possible to effect a material change, what are the means by which it can be accomplished most successfully.

[In the course of a discussion which followed the reading of this paper, Dr. Masters and Messrs. G. Paul, Watson, and G. Nicholson stated many interesting facts respecting the culture and usefulness of Cape Bulbs.]

#### CHOICE AND USEFUL PALMS.

THERE are few plants grown in our glass houses more useful than Palms. Their foliage and habit are most graceful, and they are capable of being employed in decorations which no flowering plant would fill. In the case of house decoration choice flowers are very pretty, but they lack the impressive effect of noble Palms. They are particularly appropriate in church decorations, and when confined to stoves and greenhouses they give these structures a more tropical aspect than any other plants I could name. Most of them assume large proportions in small-sized pots, or in sizes at least which are admissible on the dinner table and in rooms, and in winter especially they are excellent subjects for requirements of this kind. There are some exotic Palms which require much heat, but some of those only requiring a greenhouse temperature are as beautiful and graceful as any, while they possess the advantage of greater hardiness.

Amongst these cool-growing Palms *Seaforthia elegans* takes the lead. It grows very fast in a cool house, has a clean stem and a gracefully drooping head. The stems become 6 feet, 8 feet, and

10 feet in height, with leaves as much in extent; and then for large rooms or spacious conservatories nothing could be more effective. Another point in favour of this Palm is that it possesses a graceful habit from the first, and little plants 18 inches or 2 feet in height have all the beauty of a huge specimen. I also find the *Seaforthia* grows in a semi-dark place and bears confinement in entrance halls and rooms better than any plant I can name. We have a plant house here which is only a room with a large window in front, and the *Seaforthia* grows better in this place than any plant.

*Latania borbonica* is another fine Palm for general use. Its leaves are broader and stiffer than the preceding, but it is very handsome and easily grown. *Corypha australis* is very hardy and rather stiff in aspect, but it is exceedingly useful, especially when 3 feet or 4 feet in height. *Chamærops humilis* is perhaps regarded as the hardiest of all Palms, as it may be grown in the open during the summer season, but it develops best under glass, and when submitted to greenhouse treatment it is very pretty. *Phoenix dactylifera*, *Pritchardia filamentosa*, and *Sabal umbraculifera* are other cool house Palms of merit, but a quantity of one sort will be found as useful as a number of different species, and the one above all others which deserves to be grown in quantity is *Seaforthia elegans*. All the Palms named thrive best in a mixture of loam, sand, and charcoal. Manure is not required in the soil, but when rooted freely in small pots liquid manure, if applied once a week or so, is very beneficial.—J. M.

#### NOTES ON SOWING EARLY PEAS.

I QUITE agree with "A Kitchen Gardener" that nothing is gained by sowing Peas in November, but my experience is quite different with Peas sown under glass and transplanted to the open ground. For several years I have sown Peas on a south border in November, I have also sown some each year in January in frames, but when the weather has been too severe they have been sown in boxes and put into a vinery, and as soon as the seedlings are up, and the weather permits, they are put into a frame and hardened. When they are about 3 inches high in the boxes or frames (and the weather is favourable) they are carefully planted on a south border by the side of those sown in November and others sown in January. High ridges are drawn with the hoe on each side, about 6 or 8 inches from the row; this and sticks about a foot high, put in very thickly, help to protect them from winds, frost, and birds. I have always been fortunate in getting good weather after planting, and they have never appeared to receive any check, but they seem to take to their new quarters, and in a few days quite an improvement has been noticed in their growth.

I have never seen much difference between the November sowing and those transplanted, as to which comes into flower first; but the great difference (and which can be seen at a distance) is the evenness, strength, and crop in favour of the transplanted ones, so much so that I am this year for the first time depending entirely on those sown under glass for the first crop. These are generally a week or ten days earlier than January-sown Peas.—J. L. B., Leicester.

#### PHYSIANTHUS ALBENS.

I WAS much interested in the notice and most excellent drawing of the *Physianthus albens* which appeared on page 6 of the *Journal of Horticulture*, but I think you would like to know that the specimen sent to you by Mrs. Crowley was fruited in our conservatory here. The seed from which this plant was raised was received by me from Cannes, where it was growing on a wall in a nursery ground. I raised the plant about three years ago, but it was only after planting it out in the ground that it thrived well, and has this season grown very freely, and now has about twenty fruit still hanging, but none has ripened. I may mention that I have another plant at my house at Woodford, which flowered this summer, but no fruit has been perfected. Of the fruit here, there have only been two or three twin specimens. I may mention that as it has flowered very freely it has been greatly admired as a useful climbing plant.—COMPTON WARNER, Woodlands, Hoddesdon.

#### PYRUS JAPONICA NIVALIS.

THE Japanese Quince is represented in British gardens by several varieties, one of the best known being *P. japonica* Maulei, an extremely handsome deciduous shrub with rich scarlet flowers and unsurpassed by any other form. *P. japonica* princeps is also a fine variety, bearing large flowers, but not quite so abundantly as Maulei. There is one called coccinea, another atropurpurea, and a third rosea, all differing in the tint of the flowers as expressed in the names. Several white varieties have similarly been obtained, those termed alba and albo-cincta having been the largest known. An improvement upon these for snowy whiteness and wax-like substance of flower is nivalis, of which a spray is shown in fig. 8. This is especially useful for early-flowering in pots, as it can be easily forced and had in flower by this time; and by growing a number

of plants to be placed in heat at intervals a succession may be maintained for a month or more. The flowers are usually unattended by foliage, but occasionally, as seen in the woodcut, a few leaves are produced, and these improve the appearance of the plants. All the varieties mentioned, including the double red, can be employed in a similar manner, and if the plants are kept spurred in to form compact little bushes they are very ornamental when flowering. A rich loam with a moderate proportion of old manure constitutes a suitable soil, but the plants can be assisted as the flower buds are expanding by supplies of liquid manure.

The usefulness of the Japanese Quince as a hardy flowering shrub outdoors is too well known to need any remark, but though it is frequently seen trained to walls it is too seldom treated as a bush. In the latter form it is very pretty if judiciously pruned so as to secure

Fig. 8.—*Pyrus japonica nivalis*.

plenty of young growth each season, and dwarf bushes are admirably adapted either for the front rows of shrubberies or as isolated specimens on lawns.

### LOOKING THROUGH THE SNOW.

As I write (noon January 13th) the sun shines out, and the green grass shows again. The storm has lasted a week, and though we have not in mid-Lincoln experienced the deep drifts which surprised our more southern neighbours, the storm has been heavier and the frost more intense than any that has been registered since 1881. Yesterday the weather, as a farmer remarked, was of "all soarts," and might have been thus described, "First it blew, and then it snowed, then it thawed, and then it froze awful." Later on the thaw returned and continued all night. There was a strange darkness this morning of short duration only, which came on suddenly a few minutes before nine, after which the day again cleared and is now positively fine overhead.

Is the earth ever invisible, ever even waste and empty to the lover of Nature, and especially to the lover of flowers? It is always to the eye of imagination clothed in past, present, or coming glory. Even if hope that is seen is not hope, the hope of the horticulturist is evident always and

tangible. As the last daughter of the year dies, and this season some of our cherished Roses lingered with us exceptionally long, the fading wreath is freshened up with fragrant Violets (common Neapolitan), and already in sheltered corners pale Primroses appear glistening through the frost. The lance or rush-like foliage of some of the Daffodil, Narcissi, and Jonquil tribe are well above ground, besides pushing clumps of Crocuses and Snowdrops, and the two graceful leaves of the Anemone fulgens, patens, &c. Even under the snow we, as it were, saw them and knew they were there. Happy the man that has his own garden, his own flowers, his own ever new delight-giving hopes. I am occupied about an herbaceous border; it has long been shadowed with sepulchral Yews, tortured by Sweet Ash, a local weed as obnoxious as twitch. It is to be dug up this spring, then the last eyesore will be gone (women cannot always have things their own way at their own time), cleared of weeds and of a Berberis which overruns everything, unsuitable for a border, and already I see it gay and graceful with all that I propose and any that my more knowledgeable friends may suggest. Of course the first line is Crocus, Snowdrop, &c., Aquilegia behind Lilium candidum.

I covet double white Chinese Pæonies, perennial Lupins, blue and cream colour, great growing Poppies, with their grand glaucous green foliage. The last trio of spring or early-flowering plants I saw to perfection in the borders of the beautiful and historic parks of Oxford. What can I have beside Geums, Potentillas, Pentstemons? The last comes in a beautiful combination with Anemone japonica alba. But I do not want to enumerate, rather to accumulate, if anyone will care to suggest a small succession of easily cultivated herbaceous plants for a somewhat dry, somewhat shaded, partly exposed, partly shut in from the south.—A. M. B.

[The weather has been very variable since the above was written, inclining generally, however, to frost, which is now again severe. Slight sprinkling of snow on ground, and on Tuesday afternoon at 4.30 there were 6° frost (outside) registered by Negretti and Zambra's instrument.—A. M. B.]

### READING HERO POTATO.

I INCLINE to the belief that "Constant Reader" (page 23) has not had the true variety of Reading Hero Potato. I have grown it ever since it was first sent out, and for the last four years as our main crop. In quality and colour of flesh it is much superior to Magnum Bonum, and quite equal to the excellent late variety in cropping and keeping properties. Our soil is a light deep loam. As showing that it cannot be "Constant Reader's" heavy soil, a neighbouring gardener, whose soil is little better than clay, also grows this variety as his main crop, and has frequently expressed to me the opinion that, all points considered, Messrs. Sutton had never sent out a better variety.—W. W.

SEEING a correspondent asking in the Journal the qualities of Reading Hero Potato, I may state that five years ago I sent for half a bushel of seed to Messrs. Sutton & Sons, which gave me every satisfaction on heavy clayey loam. The variety is a first-rate cropper, very little disease, and excellent on the table. Altogether I consider the "Hero" a first-class Potato, so much so that I make it my only main crop variety, and I can keep them till the Ashleaf comes in.—JAMES BURGE.

### FARMERS AND GARDENERS.

"A THINKER'S" view of the present and future prospects of gardening and gardeners is not cheering, whilst he takes a gloomy view of those relating to agriculture. I thank him for his outspoken remarks, but I beg to differ from him in some matters both as to cause and effect.

Agriculture is declining, land is for the most part very indifferently cultivated, rents are still being reduced; some landlords have land for which they cannot find tenants, and have not the desire or capital to work it themselves, which all mean reduced incomes; but an appearance must be maintained, the stables must not suffer, nor showy men servants and domestics be reduced. Yet the hands on the farm are lessened, the garden expenses cut down, the woods and estate accounts curtailed. There is the same consuming establishment, whilst the producing is shortened, reduced labour meaning impoverished land, less produce. I need only point to one example as indicating what is meant. On one estate with which I am familiar, eight men, all married with families, were employed on the home farm, now there are four; eight men were regularly kept in the woods, now there are two, and the garden staff has fallen to four men and a boy, who have to keep order in over thirty acres of grounds and gardens. There are the same house servants, stablemen, and gamekeepers. This state of things, as your correspondent, "A Thinker," anticipated, is only making bad worse. The farmer cannot make the farm pay, the woods have ceased to be profitable, and the gardener is changed very often, three in less than three years—sure indication that bricks are expected to be made without straw. "A Thinker" rightly attributes the depression of agriculture to an extravagance which,

beginning at the landlord, descends to the farmer. It is useless seeking to maintain an appearance that the means do not warrant, inasmuch as it is had at the impoverishment of the soil, everything being taken from it, little or nothing returned in labour or fertilisers. It must fall still lower in value under such conditions, and will eventually necessitate a sale. Capital will be forthcoming to work it on new lines at a profit, and that it may now be worked to the mutual advantage of the cultivator and consumer I will give an instance. In this parish, not a hundred miles from Fleet Street, a farmer arranged with a market gardener in an adjoining parish to plant a field with Potatoes, the farmer to find the land and manure, the market gardener the seed and all labour in connection with the crop. The crop was a heavy one, both agree in its being satisfactory. The farmer had not the capital to find seed and labour, and he was deficient in the "go" of the market gardener. Why not transfer the land to the market gardener? The farmer only pays 30s. per acre, for land in an adjoining parish the market gardener pays £4, £5, and some as high as £7 per acre. The farmer keeps his phaeton, and his daughters play the piano, employs a man and boy, with odd man occasionally, and has the character of always being backward in paying, indeed figures in the county court. The market gardener only keeps a gig as principally used for business, his sons all work or manage, and his daughters never stay on his hands after they become instructed in home duties. He finds employment for as many as sixty men, women, and boys, and is renowned for his ready money transactions. "A Thinker" is right, the farmer has been ruined by prosperity, and nothing in the shape of reduced rents will save him; he needs capital to purchase stock, employ labour, and purchase fertilisers. Owing to the land hunger of the farmer in the prosperous times, medium-sized holdings were thrown to large farms. The landlord sees his error now, for he cannot draw even reduced rent with regularity, and is glad to let a tenant remain whether he attends the rent audit or not, for if he leave where are the arrears to come from, and who will take the land? Let the obviously too large farm be reasonably divided, is a ready answer. But where is the capital to come from to erect the homesteads? and if these are granted, where are the tenants? Have not the best men gone to the towns and the lands of the west? There are plenty of labourers, but with their low wages and intermittent work they are as "hard up" as any other class. What an anomalous state of things for a wealthy nation. The land will pay if well tilled, but where are those to be found who have cultural knowledge and money too? That is the crucial question.

Passing to horticultural matters, foremost comes the consideration of an over-stocked market—too many gardeners, too few situations. It has been so ever since I entered a garden forty years ago. There always were too many seeking appointments. Influence placed me in a garden; by it alone was I permitted to follow my desire to become a gardener, and I can now understand why I was treated coldly by the chief. I was to be manufactured into a gardener without a premium. I never paid one and never have taken one; indeed, I feel after thirty years' practice as head that I have yet much to learn. The premium system has much to answer for. A premium will never make a gardener, but it acts as a stimulus by which unworthy men are placed in the market and a glut created. It manufactures journeymen, a large per-centage only pass from that stage to become porters, &c., and of the remainder few give proof of the plodding industry and interest out of which the gardener is made. The worst of the premium system is that it means pushing on the giver whether he have the capacity or not in return for the monetary consideration. This is bad; still worse is the practice that obtains of a bonus being given to those having influence in procuring situations. Gardeners like those who have been under them to get good places; it says much for the gardener, it gives the place notoriety; indeed, so notorious are some that to have been at such a garden under such a man is sufficient to give a pass to the first vacancy. Surely all the best lads, all the best journeymen, and all the best foremen are not absorbed by those places that manufacture a certain number of gardeners annually. I have heard it boasted that on an average as many as nine young aspirants are placed in head situations from one noted garden every twelvemonth. This system means the ousting of other, older, and more experienced men. I blame those that take lads solely for the sake of a premium, that have a journeyman for work that a labourer could do just as well, or better, and that push foremen into head places simply because they have been under them so long as to render their staying a reproach on the credit of man and place.

What becomes of the many men changing places (and invariably succeeded by foremen from some grand place) is to me a puzzle, inasmuch as I seldom find a note of their re-appointment. They must go somewhere and live somehow. Some few get admission to nurseries, these being too full to accommodate all, even those that had been good customers. The way out of the difficulty is to aim at a higher standard and admit none to pass but the painstaking and meritorious. If an apprentice, journeyman, or even foreman shows no capacity for becoming a competent gardener, then I submit the chief should at once put in his veto instead of pushing an unworthy man into another place.

There is a method of manufacturing gardeners, which, though a prevalent one, is overlooked by "A Thinker"—viz., the many lads taken into gardens at the command of the proprietors—the sons of poor tenants, smart it may be at school and of service in the choir. The parents are poor, have a large family—it may be the breadwinner is taken away—something prompts their being given employment in gardens. The gardener must acquiesce, the progress of the pupils under such patronage is rapid, and they are pushed ahead. Gardening ought to be made a science, public examinations, certificates of competency doing away with the passes now granted upon favour as often, if not oftener, than upon the sound principles of industrial energy and skill in the profession.

I now come to the conversion of private gardens into "market gardens." The proprietor, through the depression in agriculture, the reduction of rents, the non-payment of rent, and land unlet, cannot maintain the garden in anything like the same order as formerly, necessitating a reduction of hands, wages, and general expense. This is a general case. The place must go down; instead of being highly cultivated it becomes neglected, and is neither a source of pleasure or profit to the proprietor and no credit to the gardener, even if the old gardener remain. Tell me, "Thinker," why this garden should not have its assessment reduced? Its value is less, it is not worth half as much to the proprietor as it was when he was able to maintain it in a high state of cultivation. Gardeners, if wise, will suggest to an employer of this kind maintaining the garden—i.e., the profitable part, in a state of cultivation by selling the produce, not now weeded through the reduction of the establishment. The gardener will do this through sheer necessity. He will seek to maintain his position for the benefit of himself and family, the men under him will be kept together, and the tradesmen of the locality and the public at large will be benefited by the produce, which comes as a god-send in cheapening food, especially as wages are low and employment scarce. The market gardeners in the locality may grumble—the squire turned market gardener; he pays no rent, and his land is assessed at a much lower rate than ours; to which the answer is clear—the land is his, the land with the buildings upon it are assessed at the value the assessor puts upon it, even the lawn and shrubberies are taxed, and it is difficult to tell in what the grievance consists; besides, whether the landowner sells or not, the same duty is levied on those he keeps as gardeners. It is folly to write of gentlemen's gardens not being rated. If "A Thinker" should have better luck than most of the craft, cleans his spade, retires, and adds a greenhouse to his villa, how long does he suppose it will be before the assessor pays him a visit? Try it, "Mr. Thinker," and then tell us the difference between the assessment of a glass structure erected for pleasure and that of one for profit.

I cannot see any difference between a landlord making the best use of his land by selling the produce himself or letting the land and allowing others to sell the produce they obtain. "Ah, I see how it is," "A Thinker" may say, "you sell." I do, and not a single complaint have I heard from a market gardener since I commenced, and there are those that have hundreds of acres near under similar crops. It is not market gardeners who complain, but the nurserymen. The selling means that the garden has become a producing not a consuming establishment, which makes a difference. Who gains? The owner—rent for the land, interest for the capital invested; the gardener maintains his position—nay, a higher one, from being more confidential; and the community at large. A general opinion obtains that landlords take to marketing with a view to profit. This may be right, but I do not know of an instance, and I could give several instances where selling is practised that not a farthing of profit is made. The proprietor finding the garden too large—more flowers, fruit, and vegetables produced than he needs—and directs their disposal, and considerably allows a commission to the gardener as a reward for the increased labour entailed. It is a shame to let the produce waste. Now, as giving it away would only prevent those receiving it from purchasing, in what way are they damaged by its sale? The public get as good, if not better, produce and more of it, therefore the selling business is for the general good. There is another aspect in which to look at the sale of produce from private gardens. Where selling is practised the garden is maintained in a high state of cultivation. It will not pay without this and carefully selected seeds or plants. Inferior will not sell, at least it does not pay—not even for carriage.

If "A Thinker" asks why I sell, my answer is, I was told to do so. We had produce that went to the pigs by the cartload, and was given away until we got no thanks. Now, mark, the same ground would not—did not—grow sufficient for the household only two years previously; it was a question of begging and buying, which straits some so-called gardeners are ever being put to through their own incompetency or inattention. Cultivation alone gave the increased yield, and my employer said, Sell it and employ the money in improvements. I tell you this is the most interesting part I have ever had in gardening. The greengrocers complained before they were hurt, for we kept clear of them by sending to Covent Garden Market. Covent Garden drew largely, so that out of some £200 worth of produce that would otherwise have been wasted I had £150 more to spend on the garden, for one-fourth went in expenses.

Does "A Thinker" suppose that when the working men have allotments that they will consume the whole of the produce? I think not, and they will have as much right to sell as the market gardener or anybody else. More growers, better cultivated land, increased produce, better fed and clad people, is the dream of many besides—UTILITARIAN.

AMONG the many interesting and instructive "thoughts" which have proceeded from "Thinker's" mind, and recorded in the pages of this Journal, the remarks made on the relative positions of farmers and gardeners, and the way they face adverse times, seem to the writer to be pre-eminently interesting, and true market gardeners are heavily handicapped by having to face the competition of so many noblemen and gentlemen whose gardeners are at the present time engaged in growing produce for sale. That we have reached the lowest ebb in regard to the reduction in the value of such products of the farmer as Wheat and other cereals does not appear to the writer, and it is almost certain that still more reduction in the prices of these products will have to be submitted to by the farmers of the future. That the price of beef and mutton will fall much lower does not seem so probable; indeed, it may almost be prophesied that such will not be the case, at least if trade generally attains to anything like prosperity.

The boundless stores of grain possessed by other countries enable them to offer for our consumption enormous supplies, and these will doubtless go on increasing, as we read of hundreds of millions of acres suitable for the production of Wheat being as yet untouched. No doubt in time all these virgin lands will be made to bear in abundance, and a due proportion of the produce will be available for Britain's supply. Therefore we may assume that no return to high prices for grain will be in store for the farmers of the future.

But we know that millions of pounds sterling leave this country annually in order that we may have a sufficient supply of eggs, butter, and cheese. Could we not produce more of these here to successfully compete with the importations from other lands? Is there not a large field open for enterprise in supplying fowls in large numbers and good quality at moderate prices to our teeming population?

The farmers must adapt themselves more to the times. To continue growing exactly the same crops as they did when our Colonies were only a dream; when America was just beginning to develop its vast resources; when transport was slow and attended with more danger and difficulty than in these days of railways and of huge floating storehouses, which, impelled at great speed by the wondrous power of steam, bear to our shores in a short space of time the products of lands which not so long ago were unknown or only described in a partial way in some adventurous traveller's book of exploits. Now we have the vast Continent of America at our doors and other equally productive quarters of the globe within easy reach; so that the farmer must face this ever-increasing competition.

Greater freedom in cropping, unrestricted leases, compensation on an equitable basis for unexhausted improvements, a more perfect understanding between landlord and tenant—in fact, the comprehension of the truth that their interests are identical, and let it also be added a more enterprising spirit on the part of many of our farmers; all these must be brought to bear on the farming of the future. Science must also receive more attention, and mere rule of thumb must not be blindly practised. Landlords have evil times to face at present. In many cases their incomes have been sadly reduced, but they must also adapt themselves to the times, and "cut according to their cloth."

And what of gardeners, market gardeners, and fruit and flower growers who are facing competition from abroad too? Regarding gentlemen's gardeners, there can be no doubt that they in many cases are feeling the effects of the hard times in such ways as reduction of labour and general curtailment of expenses, but in most cases they have not been called upon to accept a lower salary themselves, and this is something to be thankful for; but many of them have been turned into market gardeners, and send the produce of their labours to compete with that of men who are "making a living" by growing for market.

The latter have not only foreign competition to face, but also the home competition of the nature referred to. Certainly one of the reforms of the future should be a readjustment of the rating of gentlemen's hothouses and gardens, where such are employed in growing for market. Let justice be done, and no one need grumble. The duke or lord has a perfect right to grow for market if he likes, and when compelled to do so by hard times no one would despise him for so doing; at the same time taxation should be laid on him in equal proportion at least to the way market gardeners have to bear it. Those of our nobility who compete with market gardeners, not from actual necessity, we will not venture to discuss here.

The same conclusion must be arrived at in regard to market gardening as in regard to farming. We must "bow to the inevitable," must "put our best foot foremost," meet competition from whatever quarter it comes by increased effort, by endeavouring to grow such crops as experience teaches us are the most remunerative, and also by using every means to produce the very best quality of whatever is being grown. Some may go to the wall in the struggle, such is always happening; but let us hope that the majority will be able to "rub along," and that an increased supply will, by reason of its excellence, increase the demand, so that a due reward may be found attending the labours of those who, having found many things against them, resolutely set themselves to overcome all difficulties.

Horticulture generally, whether in connection with market produce, private or public supply, or private gratification for the love of the beautiful, seems passing through a trying time; but let us again hope that the result of all its trials may be an increased hold on the people in regard not only to the supply of their wants, but also the gratification of those feelings of admiration and pleasure which are awakened in the minds of all who are susceptible of being touched by the beauties of Nature, and who can feel elevated and refined by the sight of lovely flowers, splendid plants, and noble fruits all appealing to the higher instincts of mankind when viewed aright.—J. T. S.

#### GROS COLMAN VINE.

In answer to "A. L. G.," I have to say that if he will look again at my note on this subject I think he will find no difficulty in separating the facts from the theory. To ask me if I am "sure that it was potash alone that the Vines required" is rather too much. I have said that the Vines exhibited certain unfavourable symptoms, and that those symptoms disappeared gradually and completely on the Vines receiving repeated applications of a liquid manure which contained a large amount of potash. I also gave facts from which it might be inferred that the soil was not likely to be deficient in supplying nitrogen or phosphorus. That is as much as I

can say now, excepting that the liquid manure used was composed of one part of cow urine to about twenty parts of water.

My experience with "potassium salts" is too limited for me to feel justified in giving directions for their use. Possibly "Lathyrus," who omitted to state the form of potash he finds beneficial to fruits and vegetables in general, can supply the requisite details.

The last-named writer is perhaps justified in refusing to accept my conclusions in face of his own experience; but on the other hand I have succeeded in making Gros Colman retain its foliage in a healthy condition without shade, and he has not, although apparently he has grown the Grape as successfully as I have. Is the potash he uses in such a form as can be readily assimilated by the plants? "Lathyrus" says, "It is difficult to see why Gros Colman should need food so entirely different from others." It is just as difficult to understand why it should require shade more than others. I do not say that it requires food different from others, but that it may require more than some other varieties; and when we consider that there is probably a greater weight taken from it annually in shape of foliage and possibly, too, in fruit than from other varieties, it follows that the supplies in the soil would be sooner exhausted. I am now writing without a leaf before me, but I should say that a good leaf of Gros Colman, such as will stand the sun, is double the thickness of any other variety that is now usually grown in houses.—WM. TAYLOR.

THE annual meeting of the ROYAL HORTICULTURAL SOCIETY will be held at South Kensington on February 9th, when the ordinary business will be transacted—namely, reading the annual report, the appointment of officers for the year, and the election of gentlemen to fill vacancies on the Council. The following are nominated as officers:—President, Sir Trevor Lawrence, Bart., M.P.; Treasurer, William Houghton; Secretary, William Lee (Downside); Auditors, John Lee, James F. West, and W. Richards. The vacating members of the Council are G. T. Clark, F. Du Cane Godman, F.R.S., and Sir P. Cunliffe Owen, K.C.M., G.C.B., C.I.E., and the following are recommended to fill these vacancies:—Sydney Courtauld, A. B. Mitford, C.B., and Baron Schröder.

— WE are informed that the dinner of the ROYAL HORTICULTURAL SOCIETY is fixed for the 9th of February, and will take place in the Albion Hotel, Aldersgate Street.

— THE monthly dinner and conversazione of the HORTICULTURAL CLUB was held on Tuesday last at the Club Rooms, 1, Henrietta Street, Strand. Amongst those present were Dr. Hogg, Dr. Masters, Rev. F. H. Gall, Mr. J. G. Baker (Kew), Messrs. George Paul, Wheatstone, Bull, Upcott, Gill, Lindsell, Nicholson, Watson, Dewar, &c., &c. The discussion was opened by an interesting paper on Cape Bulbs, by Mr. J. G. Baker (Kew), which is published in another column, and was continued by Dr. Masters, Messrs. Watson, Nicholson, G. Paul, &c., and many interesting facts bearing on their horticultural aspect were elicited.

— MESSRS. SUTTON & SONS, Reading, offer a number of special prizes at the Show of the Royal Horticultural on the following dates:—May 25th, six prizes for Cucumbers and Melons. June 22nd, three prizes for Melons. July 27th, ten prizes for Cauliflowers, Peas, and Cabbages. September 7th and 8th, six prizes for Carrots and Tomatoes. October 12th and 13th, twelve prizes for vegetables and Onions. October 26th and 27th, twenty-six prizes for Potatoes, Celery, Beet, Carrots, Leeks, and Parsnips. These prizes vary in value from 42s. to 5s. Prizes are also offered at Oxford on July 30th, and at Reading on June 1st and August 26th. Particulars respecting the varieties to be shown on each occasion can be obtained from Messrs. Sutton & Sons.

— WE are requested to insert the following relative to ROYAL HONOURS TO THE SEED TRADE. "Messrs. James Carter & Co., who have supplied their celebrated Grass Seeds and other specialities to H.M. the Queen for nearly twenty years, have received the honour of a Royal Warrant appointing them upon Her Majesty's service as seedsmen. Messrs. Carter have for many years held Special Royal Warrants as seedsmen to H.R.H. the Prince of Wales, H.R.H. the Duke of Connaught H.I.M. the King of Italy, and H.I.M. the King of Portugal."

— WE are desired to state that MESSRS. WRIGHT'S BOILER CO., of Airdrie, N.B., have been awarded medals for their "Endless Flame

Impact" Hot-water Boilers at both London (Alexandra Palace) and "Inventions" International Exhibitions.

— THE annual general meeting of the ROYAL METEOROLOGICAL SOCIETY will be held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Mr. R. H. Scott, F.R.S.) will deliver his address.

— WE have received a copy of the fifth edition Mr. J. R. Pearson's "VINE CULTURE UNDER GLASS," which has been revised and edited by Mr. C. E. Pearson, and is published by Messrs. Thos. Forman & Sons, Sherwood Street, Nottingham. It is a concise, practical little work, and is a useful guide for amateurs.

— MR. SHIRLEY HIBBERD'S "GARDEN ORACLE" FOR 1886 is just issued (4, Ave Maria Lane, Paternoster Row) and, as usual, contains a variety of useful information, in addition to the ordinary calendrical matter. Lists of new plants, flowers, fruits, and vegetables are given, with selections of useful varieties and hints on their cultivation. A valuable chapter on the cultivation of hardy herbaceous and alpine plants with full lists of varieties is included in this edition, and constitutes a very useful portion of the work. Those interested in political matters will appreciate a list of the members of the new Parliament embodied in this edition.

— WE are informed that the READING HORTICULTURAL SOCIETY will hold their Spring Show on June 1st, and the Summer Show on August 26th in the Forbury Gardens.

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, Worksop, Notts, for December, 1885. Mean temperature of month 37.4°; maximum on the 16th, 53.7°; minimum on the 8th, 13.2°; maximum in the sun on the 31st, 84.8°; minimum on the grass on the 11th, 10.4°. Warmest days 1st and the 3rd; coldest day the 8th. Mean temperature of the air at 9 A.M., 36.8°. Mean temperature of soil 1 foot deep, 38.6°. Nights below 32° in shade, thirteen; on the grass, twenty-four. Total rainfall 0.81 inch; maximum fall in twenty-four hours on the 30th, 0.20 inches; rain fell on thirteen days. Average velocity of wind 11.4 miles per hour; velocity exceeded 400 miles on eight days, fell short of 100 miles on three days. Sunshine.—Total duration in month twenty-eight hours, or 12 per cent. of possible duration. Maximum duration in one day, on the 10th, 5.1 hours. We had sixteen sunless days. Dry and rather cold month. The minimum temperature was rather low, but not exceptionally so. The rainfall is smaller than in any of the previous ten Decembers. Very little snow fell. The wind was very light, except during the last few days.

— THE METEOROLOGICAL SUMMARY FOR THE YEAR 1885 is as follows, from the same correspondent:—Mean temperature of the year, 46.8°. Maximum on the 25th July, 86.0°. Minimum on the 8th December, 13.2°. Maximum in sun on the 26th July, 133.7°. Minimum on the grass on the 11th December, 10.4°. Warmest day the 26th July, mean temperature 70.5°. Coldest day the 8th December, mean temperature 23.6°. Mean temperature of the air at 9 A.M. 47.3. Mean temperature of the soil 1 foot deep, 47.9°. Nights below 32° in shade seventy-six; on grass, 133. Total rainfall 24.70 inches. Maximum fall in twenty-four hours on the 23rd October, 1.67. Rain fell on 181 days. Snow fell on twelve days. Sunshine, total duration in year 1119 hours, or 25 per cent. of possible duration. Maximum duration in one day, on the 27th June, 14.0 hours, or 84 per cent. of possible duration. We had 113 sunless days. The year may be described as uniformly cold, of average rainfall, and very deficient in sunshine. February was the only month with temperature above the average. The number of frosty nights is above the average, but has been exceeded. Sunshine has been very deficient throughout the year; the only really bright month was September. The number of sunless days is twenty-eight more than in any previous year. Northerly winds have been rather more frequent than usual.

— AN American paper states that PEACH TREES often attain a much greater age and size than is generally supposed. In his address before the Pennsylvania Horticultural Society, President Stitzel stated that he had known trees in Maryland from sixty to eighty years old still in good bearing condition, while one, supposed to be nearly one hundred years old, was 2 feet in diameter near the ground, and was still productive.

Cases are related where Peach orchards in grass land which had ceased to bear and were apparently worthless had been restored to vigour and productiveness by cultivating and manuring the soil.

— AN extensive MARKET GARDEN in SOUTH WALES is thus described in the *Illustrated London News*: "Llysonen Gardens, seven miles from Carmarthen, are the property of Captain Mansfield, R.A., where he pursues the art of floriculture successfully. He has an area of 200,000 feet of glass, with a proportionately large staff of gardeners, painters, glaziers, masons, carpenters, and firemen, many of whom reside in very pretty cottages which the captain has built for his people. The mechanical apparatus for supplying water and heat are the most perfect that could be invented; and the coal used is the anthracite coal, which gives tremendous heat. There are no less than six miles of hot-water piping passing through the numerous stove and plant houses. Thousands of Roses in pots are already in bud. A house is devoted to Lilliums, another to Orchids, while others are individually devoted to Geraniums, Pelargoniums, Cinerarias, and sweet-scented foliage plants. There are 100,000 pots of Lilies of the Valley for forcing. The Camellias are magnificent, and a house full of Maidenhair Ferns is a sight not easily to be forgotten. The forcing houses were already rich in blossom, and thus eighteen large houses were devoted to flowers. In the Peach house 10,000 pots of Strawberries are forced each year. There are many hands employed in preparing and packing the flowers for the London market."

— WRITING to the *American Florist*, Mr. Peter Henderson gives the following account of a CRIMSON CALLA, but it must not be mistaken for a variety of *Richardia*:—"I give the story of a crimson Calla (*Arum palæstinum*) of which I became the fortunate possessor a few years ago. A lady called on Messrs. Young & Elliott, seedsmen of New York, and stated that she had a crimson Calla in bloom, and she wanted to sell it to them for 100 dollars. Mr. Elliott suggested that she bring it down to one of his auction sales and let it be sold there. This she agreed to do, and down it came in full bloom, crimson sure enough. Mr. Elliott expended a wonderful deal of eloquence in trying to get someone to bid 100 dollars for it, but was obliged to take my first bid of 100 cents, which was gradually run up to 1000 cents, and I became the possessor of the crimson Calla. I then secured all the remaining stock from the lady consisting of about a dozen small plants, and grew it until I obtained over 100 plants, but in some way by running it against the grain I lost the whole stock of it. I do not know to-day if there is a plant of the crimson Calla in the country, although if it could be grown easily it would be a most interesting plant. It is of a rich crimson maroon, nearly as large as the flower of the dwarf Calla, and, unlike most other plants of the *Arum* class, it has a rich fragrance, somewhat similar to the Violet."

— THE Immigration Office, Sydney, New South Wales, periodically issues a sheet containing miscellaneous information relating to the colony, and from one just received we extract the following paragraph respecting NEW SOUTH WALES TIMBERS. "Probably no country in the world possesses finer or more durable hardwoods than New South Wales. Her Pines and Cedars, valuable though some of them may be, yield the palm to those of other lands; but her Ironbark and Blackbutts rank, for durability and strength, second to none on the globe. Singularly enough, all the principal hardwoods used in the colony are myrtaceous trees—that is, members of the great Myrtle family, which, according to Professor Balfour, is divided into five tribes, containing seventy-five known genera and upwards of 1800 species. Members of this great family are natives chiefly of warm countries, as South America and the East Indies, although many are found in more temperate regions. Some of the genera, such as the Eucalypts, are peculiar to Australia, although they have been successfully transplanted in Europe and the East, and in the Campagna at Rome, on the borders of Portugal—where they have been planted by the vigneron for the making of casks; and even on many of the hill stations of the Punjab and Madras the wandering Australian may recognise the tall rough stem, leek-green leaves, and strong perfume of the sylvan denizens of the sunny south. Eucalypts, which constitute at least three-fourths of New South Wales timber-producing trees, furnish us with the bulk of colonial hardwoods. Ironbark, Black Butt, Blue-gum, Stringy-bark, Swamp Mahogany, Tallow-wood, and Yarrah all belong to the same remarkable genus, although they differ from one another in many ways, and in none more so than in their rate of growth, the Blue-gums and Blackbutts being very rapid growers, while the Ironbark and Box take a very much longer time to mature. The remainder of hardwoods are principally Angophoras, or "Apple trees," most of which are subject

to "gum-veins," Tee trees, *Tristanias*, and *Syncarpias*, better known as Turpentine trees, but all members of the Myrtle family, and all growing in the open forest, and very rarely in the bush or the scrub."

### PEAS FOR PROFIT AND EXHIBITION.

AS we have entered upon the new year, which I hope will be a happy and prosperous one for all, especially for all gardeners, and being an amateur gardener myself, I thought as the season is fast approaching for sowing seeds a few remarks upon Peas for profit and exhibition would be useful to some young gardeners.

The first thing I would recommend is giving your seed orders at once to facilitate the seedman's work. I advise obtaining sufficient seeds for a small sowing of the following varieties:—William the First, Laxton's Earliest of all, Laxton's Evolution, Laxton's Charmer (a new one this year, I think the best Mr. Laxton ever sent out), Carter's Telephone, Carter's Stratagem, Carter's Pride of the Market (three very good Peas), Webb's Wordsley Wonder, and Culverwell's Telegraph. I think the above-named varieties would be very hard to be surpassed either for profit or exhibition.

The next work is to prepare the trenches, as I have found from practice that it is almost impossible to grow first-class Peas either for exhibition or culinary use unless a trench is made, say 12 inches wide and about the same depth, place the soil that comes out of the trenches upon the east or north side of the trench, and it will then shade the Peas from cold cutting winds that frequently otherwise destroy good crops of Peas. Afterwards fill the trench with rich manure; either old or new will do, as I have tried both and have sometimes thought I have grown the best Peas from the new manure, but the latter comes from the piggeries, and therefore is very good. Let the manure be trodden down in the trenches until it is reduced to about 9 inches in depth; then place in the trench about 1½ inch of soil, a good dusting of unslacked lime that will keep the worms and slugs from destroying the seed. Sow the seed at this time of the year, cover the seed with about 1 inch of soil as fine as it can be made, adding to that if possible about half an inch deep of coarse ashes or small cinders. This I find is a great protection to the plants from slugs and other enemies. I always keep some fine unslacked lime by me, and if slugs attack the plants I dust them very freely with the lime; in fact, I find Peas are very much better if dusted with lime about every fourteen days until they have reached about half their growth.—HY. MARRIOTT.

[Our correspondent, who is well known as one of the most successful cultivators of Peas, obligingly offers to send further notes on growing them to perfection and staging pods for exhibition. We shall readily publish a communication on this subject.]

### ROSE MILDEW—NOTES ON GYPSUM.

IN reply to Mr. Kruse, we gave nearly all our Roses a dressing of gypsum on March 4th, 1885; but as we had so little rain during the summer I do not think it was sufficiently washed into the ground to reach the roots to give it a fair trial, but we certainly had less mildew on our Roses last year than usual. It would have been better put on in the autumn, so that the winter rains could have washed it well in and dissolved it, as I think it requires a quantity of water to dissolve it, so that I expect to see a greater improvement from it next summer than the last; more especially as I think it is what our soil requires, for it is rather light and it has been heavily manured for several years.

I also tried it on Onions, Peas, Broad Beans, Shallots, and Strawberries without perceiving any improvement, although a piece was marked off in the centre of each plot and carefully preserved. I also sowed some in the drills with the late Peas, hoping it might prevent mildew on them; but it seemed to make no difference whatever, although the Peas were kept well watered. The only improvement in vegetables was on a piece of Canliflower (autumn-sown), half the piece being sown with gypsum, the leaves of the plants on which grew much larger than the others, and most of the heads came in before the others, but as they were wanted in the house when quite small no fair comparison could be made.

Now if gypsum will prevent mildew on Roses, why should it not on Peas? And if gypsum contains 30 per cent. of lime and 40 per cent. of sulphuric acid, and the rest water, which of the two will prevent mildew, or is it both? Either of these separate we could get at much less cost than we could gypsum, as ours had to travel about 150 miles.—J. L. B., Leicester.

### THE PAMPAS GRASS.

THERE is no more pretty or useful plant in our gardens than the Pampas Grass, but unfortunately, as a rule, it is confined to large gardens and parks, few amateurs and villa gardeners ever thinking of introducing it. Why this should be so it is difficult to understand. That it looks well, and is highly suited for the embellishment of large gardens, no one can deny; but that it ornaments small gardens to an equal extent is as certain, and I am greatly in favour of its being more generally planted.

Isolated specimens are very effective, and when upon green turf they are more graceful than any bush or tree. They are also attractive in corners, or amongst shrubs in groups, or as boundary bands. The foliage is sweeping and graceful, and in early autumn, when the magnificent feathery plumes appear, they become more and more conspicuous. These heads are highly ornamental on the plants, and when cut and dried they

are extremely useful for house and church decoration in the winter time. We use them freely in large flower vases, and the other day we put some scores of them into the church. They were effective in the extreme. The plan of cutting the heads required for purposes of this kind before they quite expand from the sheath which envelopes them at first is a good one to a certain extent, as the heads turn out white, but they also come smaller than when allowed to develop fully. For this reason we do not cut all we require in the young state, but allow many to grow to the fullest extent, then they are cut before beginning to wither in any way, and they are blanched to become almost as white as milk by confining them in an air-tight place and burning sulphur with them. It is astonishing how confinement with sulphur fumes whitens them, and if they are held before a strong fire afterwards, or at any time when they are damp, they will expand like a damp feather when exposed to the influence of a quick drying fire. The foreign Pampas heads, which are chiefly sold in shops, are fine specimens as a rule, and their size and colour surpass those generally grown in this country; but good cultivation will produce heads as fine as any which it is possible to buy, and anyone who puts the plants into rich deep soil need never have to buy plumes. The present is the best of all times to plant. They are very hardy, and may be introduced in all quarters. They thrive well inland or near the sea, in exposure or shelter, in smoke or the purest atmosphere, and I never knew them to fail and miss a season in producing their showy plumes. Some are inclined to cut away some of the leaves from the plants during the winter and allow new growths to appear in spring, but this is a great mistake, indeed I once knew a fine plant ruined by this, and the best of all ways of treating established plants in winter and at all times is to leave them alone.—J. M.

### FORESTRY.

MR. JOHN R. JACKSON contributes a paper to *Nature* upon this subject with some interesting notes worthy of reproduction.

The report of the proceedings of the Select Committee on Forestry which sat during the past summer does not, perhaps, throw any more light on the condition of forestry in this country than was possessed before the appointment of the Committee, for the substance of the evidence given is for the most part to be found in the various works and reports on forestry that have appeared from time to time during the past few years; nevertheless the evidence of such men so well versed in forest conservancy, especially with regard to India, as Dr. Cleghorn, Col. Michael, Col. Pearson, and Mr. W. G. Pedder is of much value, as it brings together in a collected form information that has hitherto been much scattered.

The subject of forest produce is one that is but little understood or even thought of by people in general. It is supposed by most people to relate only to the supply of timber, which indeed of itself is of very great importance; but when we consider the other products—such as gums, resins, oils, fibres, and such like—the enormous money value becomes more apparent, as well as the great importance of the forests as sources of many absolute necessities of life. The evidence of Col. Michael fully illustrates this, and is especially valuable from this point of view. Taking the subject of Indian timbers alone, the value of teak was fully set forth when it was shown to be unequalled for the backing of ironclads and for ship-building generally, as offering the greatest resistance of any known woods. Questioned as to whether teak was capable of being brought into this country as a commercial article at a remunerative profit, Col. Michael replied that, judging from the price realised for some logs sold at the Forestry Exhibition at Edinburgh and from other information obtained, no doubt existed that the trade in teak might become a very remunerative one. It was shown further that in 1883 £647,000 worth of teak was imported into England; but Col. Michael also touched upon what, if put upon a proper footing, might equally, or perhaps more so, become a source of revenue to India and a boon to this country—namely, the introduction of the more ornamental woods for cabinet purposes. There is, of course, always a steady demand for British-grown timbers such as oak, elm, ash, maple, &c., but these have to be supplemented by foreign woods of a more ornamental character, and of these, mahogany, rosewood, ebony, satinwood, and such like are the best known. From amongst Indian timber trees a long list might be made of woods which are now almost unknown out of their native country—such, for instance, as the East Indian Cedar (*Cedrela toona*), which is a reddish-coloured wood with a splendid wavy or feathery figure; the tree is also found in Australia, where the wood is highly valued; the Padouk (*Pterocarpus indicus*), the deep-red-coloured wood of which attracted so much attention at the Edinburgh Exhibition last year; the Malabar Kino Tree (*Pterocarpus marsupium*), also a finely marked deep-red wood, several species of *Terminalia*, durable woods of a brown colour with darker brown markings. Many others might be mentioned, but the most beautiful of all the Indian woods for its ornamental character is the Chittagong wood (*Chick-rassia tabularis*). This is of a brown colour, with transverse lighter silvery-brown wavy markings, which impart to it a varying depth of light and shade, which, when polished, imparts a peculiar and charming lustre. All these woods take a high polish, and would be invaluable for cabinet work. Fine specimens of these and many others are in the collection of Indian timbers exhibited in the No. 3 Museum at Kew.

On the question as to the durability of the Scotch Fir (*Pinus sylvestris*) Col. Pearson gave an opinion which is worth quoting. He says:—"I think myself that as the value of the foreign imported timber increases as it must do as the quantity diminishes, people will come to appreciate more the Scotch Fir, because I know many barns which have been

boarded with Scotch Fir for twenty years, and which are standing perfectly well; but it is convenient to get the imported boards ready sawn out, and where the people can get them cheap they do not pay attention to the Scotch and home-grown timber. But, speaking for myself, I should say that Scotch Fir is a perfectly good wood as long as it is sufficiently mature, and I think, as foreign wood becomes dearer, as it will in a few years, English timber and Scotch timber will become of a value which it has not now."

On the general subject of the proposed Forest School Col. Pearson expressed himself in favour of a Chair of Forestry at the Edinburgh University, but he further stated that he had no actual faith in lectures in the school unless illustrated by practical instruction. "If," he says, "you tell a man in the lecture-room that such and such consequences will take place, and do not show him the consequences on the spot, he does not believe anything about it; it goes in at one ear and out at the other; he will think it all nonsense; but if you want to impress your teaching upon him, you must take him out into the forests and show him the operations of Nature." Regarding the extent or scope of the School, Mr. Thielton Dyer, in reply to Sir Edmund Lechmere whether he would not make the School of Forestry applicable to India and the Colonies as well as to our own country, said, "I should like to get all the fish possible into the net, and if we had such a school to make it as useful as possible, I think it is surprising, considering how large is the interest of the English race in forestry, that except in India we have taken no kind of active interest in the subject: although we own more forests in the world than any other race, we are at present, except in the most piecemeal fashion, absolutely washing our hands of the whole business." Mr. Dyer, in his evidence, further pointed out by way of illustration a few of what are usually called the minor industries of forest produce, which in the aggregate become of considerable national importance.

It is to be regretted that the Committee was not nominated at an earlier period of the session. The first sitting was on July 14th, and at the two subsequent sittings on July 21st and 24th, witnesses only were examined. The report of the Committee refers to the impossibility of concluding their investigations during the Session, and "recommends that a Committee on the same subject should be appointed in the next Session of Parliament."

### CYPRIPEDIUM INSIGNE.

THIS is a favourite Orchid here now. It flowers unfailingly at this season, and as the plants are very hardy and the blooms substantial it is very useful. Our plants have not been potted for two years. The largest one is in a 10-inch pot. The leaves of this one droop over and almost hide the pot, and it is now bearing forty-three blooms. Another plant in an 8-inch pot had twenty-four flowers; this one was placed in a room four weeks ago, it is there now, and the blooms are as fresh to-day as they were on the 26th of November. This, I think, is one of the greatest recommendations a plant could possess. When the flowers are cut they are equally useful, as they will remain fresh for a fortnight at least in a glass of water. Some time ago *C. insigne* was grown in a warm house, but the excellent plants I saw in Mr. Cypher's nursery at Cheltenham two years ago induced me to alter the treatment for them. These were allowed to remain in a cold frame from May until the end of September, fully exposed to the sun and liberally ventilated. It is simple and easy, and a plan which any amateur with a cool frame and a small greenhouse could adopt with success.—J. MUIR, *Margam*.

### PLANTS CERTIFICATED IN 1885.

MESSRS. H. CANNELL & SONS.

THE Home of Flowers has long been a prolific source of novelties, and every year some of sterling merit are added to the lists of popular flowering plants. Whenever a variety of great promise is obtained it is extensively propagated, and a large stock is quickly secured to supply the numerous demands, and not unfrequently visitors to Swanley may see a whole house devoted to one such novelty. Owing, however, to the number of specialties at the nursery, there is a surprising succession of interesting floral displays throughout the year. At one time we find *Pelargoniums* predominating, at another *Primulas* seem to occupy the greater space, or *Cyclamens* and *Fuchsias* are in the majority. Later we see the brilliant *Tuberous Begonias* in their thousands, and conclude the season with a multitude of *Chrysanthemums*. These are a few of the principal features of the glass department; to them might be added many others, such as *Verbenas*, *Bouvardias*, and *Petunias*, to which much space is devoted. Then, too, the spring and summer months bring a grand succession of outdoor flowers, *Roses*, *Dahlias*, *Pansies*, *Violets*, *Pentstemons*, and all the best hardy herbaceous plants, every square yard of ground being occupied with garden treasures innumerable. With such resources at command, and a widely extended correspondence, it can be readily understood that Messrs. Cannell & Sons enjoy especial facilities for obtaining novelties, of which they fully avail themselves.

Reviewing those which have received honorary awards at the various metropolitan shows this year, the following deserve particular notice for their distinctness and beauty. *Tuberous Begonias* have been increased by eight fine varieties, of which several are doubles of great merit. Of these may be mentioned *Antoinette Guerin*, white, neatly formed; *Blanche Duval*, creamy white, with a pink tinge before expanding; *Gabrielle Legros*, pale yellow, delicate and beautiful, of excellent form and substance; *Marchioness of Lothian*, creamy white, the blooms large, full, and drooping, well adapted for baskets; *Picotee*, a bright rosy-tinted

variety, with a clear white edging to the rounded petals; and *Louis Bouchardet*, scarlet, free and handsome. The single varieties include the following—*Earl of Bessborough*, a dwarf free variety, with bronze yellow flowers; and *King of Crimson*, crimson scarlet, very large rounded flower, bold and handsome.

The *Swanley Chrysanthemums* have been referred to at some length recently, and it is only necessary to mention the names of the principal varieties. The *Japanese Beauty* of *Swanley* is one of the best that have been certificated this year; it is of fine substance and a novel shade of colour—a soft rosy lilac. It appears likely to make a good exhibition variety, and we may expect to see it at some of the leading shows next November. The *Japanese Anemone* variety *Catherine-wheel*—white with a sulphur centre—and the single *Queen of the Yellows* are also notable varieties from the same establishment.

A trio of good *Dahlias* gained certificates for Messrs. H. Cannell and Sons in the past year. Two of these are single varieties—namely, *Eclipse*, rich deep scarlet yellowish at the base of the florets, which are round, and the general outline is good; and *Faust*, of a peculiar bright red tint, very distinct, and, like the preceding, of excellent form. The third variety is *Germania Nova*, a decorative variety, with compact blooms, formed of numerous acute closely packed bright rose florets. A pair of *Verbenas*, *Dr. Feyerlin* and *Purity*, the former rich purplish crimson and the latter pure white—have been certificated, together with a superb single white *Primula* named *White Perfection*; the handsome pure white *Carnation*, *The Governor*; and the old but useful *Centropogon Lucyanus*.

It has already been remarked that there is a succession of floral exhibitions at *Swanley* that render the nursery attractive at all seasons, and a few notes upon the leading features there at the present time will show that even in such a season as this flowers can be had in abundance. The winter-flowering *Zonal Pelargoniums* are still bearing plenty of blooms, and the usefulness of the plants is very great, for they have provided a brilliant show in the houses since October, the singles being the brightest and best for grouping and general effect, while the doubles are invaluable for cutting. The latter are, however, now getting past their best, though there is no lack of singles to choose from, some of the most striking being as follows—*Scarlet*: *Ajax*, *Plutarch*, very dark; *Aurore B. reale*, light scarlet, large bloom; and *Lord Rosebery*, bright. *Crimson*: *Zelia*, *Octavia*, and *Ferdinand Kauffer*. *Imogene*, salmon; *Norah*, blush, very fine; *Kate Greenaway*, pink, large and deep; *Lady Read*, pink centre, white edge; *Swanley Gem*, rosy salmon, white eye; *Edith Little*, blush; *Eurydice*, pink, white centre; *Mary C. swell*, blush; and *Constance*, pink, a handsome variety. The double varieties comprise the following—*Colonel Flatters*, crimson; *Laknal*, crimson; *B. le Noir*, dark crimson; *Mrs. Cordon*, cerise scarlet; *Lord Mayor*, purplish crimson; *Lord Derby*, pink; and *F. V. Raspail*, scarlet. All these are reliable winter-flowering varieties, and form a selection of much value.

*Primulas* have two or three houses devoted to them, and are in superb condition, vigorous plants, with plenty of bright or puce flowers. The *Swanley* strains of red, purple, white, and blue form the bulk of the stock, and possess their distinguishing characters true and strongly marked, as much care has been given to the selection and fixing of the types. In addition to these, however, there are some choice named varieties, such as the large handsome delicate blue-tinted *Princess of Wales*, the curious lilacina, the charming Fern-leaved delicate, the enormous rosy crimson *Mammoth*, the largest-flowered variety of all; the dark-stemmed *Queen of the Whites*, and a wonderfully bright form called *Coccinea Improved*, which was obtained from *Swanley Red* crossed with the old *Coccinea*, possessing the size and substance of the former with the brilliant colour of the latter somewhat deepened. Then of double *Primulas* there is the invaluable old *Double White*, affording its blooms by the basketful, and other doubles of the *Gilbertian* type, such as *Mrs. Laxton*, white; *Earl Beaconsfield*, pink; *Marchioness of Exeter*, white; *Miss Eva Fish*, and *Annie Hillier*, blush, very delicate and pretty, are also flowering plentifully. The curious Parsley-leaved *crispata alba plena* is worth growing, as it is quite distinct in foliage from any of the other *Primulas*, but the flowers are not so useful as those of the old *Double White*.

Houses of *Cyclamens* in flower form another feature, the variety *giganteum* being extremely beautiful for the size and substance of the flowers. The stock of seedling *Cyclamens* for another season is astonishing. Thousands of healthy little plants about three or four months old in small thumb pots are those that a year hence will contribute to the floral display what the others are doing now. *Bouvardias* are in similar numbers, the larger plants flowering freely, such as *Vreelandi*, white; *Priory Beauty*, pink; *Hogarth* and *Dazzler*, scarlet; with the double pink *President Garfield*; white *Alfred Neuner*, and scarlet *Sang Lorraine*. A pretty group is arranged in one of the houses, composed of dwarf *Oranges* in pots, and which, for ornamental purposes, might be much more freely employed than they are at present. The pots are mostly 32-size, and the plants from 9 to 12 inches high, bearing from six to twelve fruits, that ripen gradually and remain on the plants for a considerable time.

Winter-flowering *Begonias* occupy much space in the same house, and those who wish to increase their supply of flowers in the early months of the year cannot do better than procure a good selection of such *Begonias*, for they are easily grown and exceedingly floriferous. The *semperflorens* varieties stand at the head of the list, comprising the ordinary form, with *gigantea carnea*, a deep rosy red when opening, and paler when expanded; and *gigantea rosea*, similar in habit but having delicate rosy pink flowers. The hybrid *B. Carrieri* is very free and compact in habit;

the well-known *B. nitida*; *B. Greigi*, small white flowers, neat and pretty foliage; *Ingrami*, *fuchsioides*, *Knowsleyana*, *Digswelliensis*, and *floribunda multiflora*, similar in habit to *B. fuchsioides*, but with pale pink coral-like flowers, are all charming *Begonias*. A distinct variety of the *manicata* type, named *aureo-maculata*, has large leaves boldly spotted with bright yellow. There is a grand stock of Tree Carnations, and a large proportion of that useful yellow *Pride of Penshurst*, which has neatly formed flowers of a bright soft puce tint, and is much superior to the majority of

rapidly increased to meet the enormous demand. There are very few *Chrysanthemums* left in flower now, but one is just developing its blooms, and is considered by Mr. Cannell as the best of all late-flowering varieties. It is the large white *Anemone Virginale*, which flowers naturally at this season, and with a little special treatment might be had much later. It is strange that it should be so seldom seen grown for this purpose, and we did not observe an example of it at the National *Chrysanthemum Society's* Show of late varieties at the Westminster Aquarium recently. A group

FIG. 9.—NEW CHRYSANTHEMUMS.

varieties of the same colour. It is also of good constitution, flowering freely and continuously over a considerable period of the winter.

The Tuberous *Begonias* to which so much attention is now paid are still resting, but preparation is being made to start them, and there will soon be plenty of work in potting. The tubers are very carefully treated, and no doubt often success is dependent upon this in no mean degree, the great point being to prevent their injury by mildew. The most engrossing work just now is propagating the *Chrysanthemum*, of which many thousands of cuttings are already inserted, and their numbers are being

of varieties to which Mr. Cannell has given some attention are those he terms "ladies' *Chrysanthemums*," and of which some are represented in fig. 9. These comprise single varieties chiefly with a few of the *Anemone* type and some small distinct *Japanese*. They are novel both in form and colour, and one—that at the upper part of the figure, named *Catherine-wheel*—was certificated last year. The ray florets are white and the centre golden yellow, a pretty contrast. The others are "*Crushed Strawberry*" on the right hand side of the figure, of a reddish tint; *Lady Churchill* on the left, yellow, with reddish bronze tips; and *Lady Dilke*, a small

Japanese variety of a bright rose colour, whitish in the centre. They are all distinct and attractive varieties.

### NOTES ON SOME GRAPES.

IN 1874 a house of Muscat of Alexandria Vines was planted here. The border was made of what was considered first-rate loam, rather inclined to clay than to sand. The drainage of the site was as perfect as it could be made, and the average depth of the soil was 2½ feet. There was no manure of any description put in it except ground bones and horn shavings. The progress of the Vines for several years was most satisfactory—in fact, they made splendid Vines in a very short time, and for several years brought very fair Grapes to a certain stage, but never finished them to my satisfaction. Always in autumn the foliage became spotted and scorched, decayed prematurely, and of course the Grapes shrivelled.

In the same range and in exactly the same soil other varieties of Grapes, such as Black Hamburgh, Gros Colman, &c., were planted contemporaneously with the Muscats, and without an exception they all did remarkably well and continue still to do so. Various remedial measures were adopted in the case of the Muscats; but not proving quite satisfactory, in the autumn of 1883 a trench was taken out right across the border at a distance of 9 feet from the boles of the Vines, crashing through every root, where these were numerous and in perfect health. Then the soil was carefully removed up to the boles of the Vines, preserving as many roots as possible. The border was made shallower by 10 inches by adding broken bricks and rough gravel to the surface of the site. The strong roots were cut back severely, and laid in soil consisting of exactly the same sort of loam as they formerly grew in, but with a considerably greater amount of lime rubbish, charcoal, &c., than was put into the original border, for the conclusion was arrived at that the evil arose from the border being too deep and not open enough for the great rainfall of this district—sometimes nearly 6 feet in a year.

In 1884 the growth was not very strong, but the foliage was maintained to the last and ripened perfectly. The Grapes ripened much better, and did not shrivel. In 1885 the Vines made stronger growths than ever before, carried their foliage till it ripened to the amber colour of a Maple, and the crop of fruit was of course in proportion as to quality. This experience may be of use to some of your numerous readers similarly situated.

Black Hamburgh and Gros Colman, as well as other varieties, including the Duke, seem to revel in the strong well-drained loam 2½ feet deep. I find Gros Maroc a very inferior Grape in every point except colour to Gros Colman when grown in Muscat heat. The former I have not in a cool house, and the little there is of it is a graft on a Muscat stock. I consider it a watery flavourless variety. Some consider Cooper's Late Black to be identical with Gros Maroc. I should doubt that verdict very much, but shall be in a better position to offer an opinion on the point next season.

It will perhaps be remembered by some of your older readers that in 1860-61 I fought a pen-and-ink battle with several writers, among others the late Mr. Cramb of Tortworth, in relation to the Bowood Muscat, I maintaining that it was quite distinct from the common forms of Alexandrian Muscat, and the other writers denying this. My opinion was never shaken by anything that has been advanced to the contrary, and I was not a little interested to find an experienced Grape-grower pointing out the difference between the Bowood and Muscat of Alexandria in the calendar in a contemporary recently, and in almost the same words—at least, to exactly the same effect—as I used a quarter of a century since. Mr. Coleman states that he had his Bowood direct from Bowood, and so I received the Vine I wrote of in 1860. Mr. Coleman points out now, just as I did then, that it is earlier and that it has broader bunches and rounder berries. You, Mr. Editor, make Bowood and Muscat of Alexandria identical. In a sense you are correct, but they are perfectly distinct varieties—more distinct than any two varieties of Black Hamburgh I know. I note, however, that in your select list you give Bowood and Muscat of Alexandria. Since I came here I have bought what was called Bowood Muscat, but have never had it true. As it is so good a setter and earlier than Muscat of Alexandria I should like and hope now to have it again.—DAVID THOMSON, *Drumlanrig*.

[The Bowood Muscat Grape is one of those pomological puzzles that crop up from time to time, and which give rise to much discussion before they are effectually solved. The distinctness of this variety and its identity with White Muscat of Alexandria have already been subjects of heated discussion. The late Mr. Cramb of Tortworth lost his temper and nearly lost his head over it; and after the question was thought to have been settled it turns up again after a lull of nearly a quarter of a century upon the authority of two noted cultivators whose opinions always claim a patient

hearing. We saw one of the first bunches the Bowood Vine produced, and on reference to our note at the time we described the berries as oval inclining to Pear shape. In the plate issued in the volume of *The Florist* for 1857, which was then edited by Mr. Spencer, who raised the Bowood Muscat, the berries are there represented as long oval, the description in the text being "oval and sometimes Pear-shaped." Mr. R. Thompson describes them as "very large, oval, inclined to obovate." Mr. Coleman, it seems, now says they are rounder than Muscat of Alexandria. The most characteristic feature is that which both Mr. Thomson and Mr. Coleman rely upon, and that is its earliness. We shall be glad to hear the opinion of some other of our experienced readers on this subject.]

### NOTES ON CHRYSANTHEMUMS.

MESSRS. ORCHARD AND MOLYNEUX are both of opinion that Japanese Anemone-flowered are not admissible in a stand of the orthodox Japanese sorts, and it also appears that our "regular judges," whoever they may be, would disqualify an exhibitor who infringed this unwritten law. The question is, How did these Japanese Anemones originate? If they owe, as I believe they do, as much of their parentage to the Japanese as to the Anemones, or, to be plain, are a distinct natural cross between the two, surely they have as much right to be admitted in one class as in the other. They are simply relegated to the Anemone section principally because they are most wanted or there is more room for them there, Japanese varieties being really too plentiful. For somewhat similar reasons several of the reflexed Japanese varieties may well be admitted into the reflexed section, as here there is also a paucity of colour. The time is not far distant when we shall have a grand mixture, one section running into the other, and the Chinese, which include the incurved and old Anemone sections, are evidently largely contributing to the creation of new so-called Japanese and other sorts. As instances of this I have only to point to the Japanese Anemone-flowered and the semi-globose Mrs. Todman, while Comte de Germigny and, in a lesser degree, Japonais evidently have Chinese blood in their veins.

As Mr. Orchard rightly remarks, the line must be drawn somewhere, but I maintain that this unpleasant duty should not be left to the judges, but it should be done authoritatively. There ought to be no difficulty about it any more than there is in the case of the Rose. Numerous practical growers doubtless will disagree with my views, but, as I previously mentioned, a well-informed authority expressed the opinion that we acted rightly in the matter.

Mr. Molyneux infers that I have formed a very poor opinion of the merits of Lord Alcester, and hints that the plants were not well grown, but he is wrong in both surmises. The plants that produced the mal-formed blooms were extra strong, standing fully 5 feet high, and the buds were very promising, yet proved extremely disappointing. The blooms were very large, but if Mr. Molyneux or anyone else could have dressed them into good form, all I can say is that they are very clever dressers indeed. We had plenty to practise on, both on and off the plants, but failed completely with them. It is a fine variety all the same. With regard to the sport from Mrs. Forsyth, I can only say that it much resembles its parent, and I do not think such an experienced and well-known grower and exhibitor as Mr. Bradner would make any mistake in the matter; at any rate, I should not, with my comparatively short experience in Chrysanthemum culture, venture to question his ability to "rightly name" the parent of the sport. Mr. Molyneux shall have an opportunity of judging for himself as to the merits of the incurved Chrysanthemum John Bradner.—W. IGGULDEN.

### REVIEW OF BOOK.

*The Golden Gate and Silver Steps*, by SHIRLEY HIBBERD. London: H. W. Allen, 4, Ave Maria Lane.

WHATEVER emanates from the pen of Mr. Shirley Hibberd is either instructive or amusing. In the volume before us he has gathered together a number of what used to be called "fingitive pieces" which have appeared from time to time in various publications, and they may all be classed in one or other of these categories. The amusing certainly predominates; but there are also among them themes that stir the heart and stimulate the finer feelings of our nature, notably the poem "Water-creases." It reminds us of Thomas Hood.

A citation from the chapter of "The Philosopher's Garden" shows that quiet humour is not incompatible with sensible hints.

At an early age my father took me to see the philosopher's garden. I am sure he was attracted by the feeling that prompts many people to take their children to see pantomimes. They take them because they want to see the pantomimes themselves. It was so in this case, I am sure, though I must say on behalf of Dad that he made as many opportunities as he could for me! and blessed be his memory for all he did! The philosopher had invited him to see the garden, and he pretended (bless his pardonable vanity!) that he went for my sake, when I knew at the time he was on a sharp look out for his own individual gratification. However, we did go; and that constitutes the first chapter of this dull story. I remember we were most cordially received by the members of the philosopher's family; and I remember, too, I trembled with fear of meeting the philosopher, for I expected he would stand on a pedestal high above our heads, clad in scarlet robes dotted with cabalistic figures, with a wand in his hand and a crown on his head, and a most awful voice like thunder in the cellar, as I had seen (and heard) the representation of a sorcerer in a waxworks exhibition that

had a week previously pitched a tent for itself in our village. Into the garden, of course, we went, and very soon a smart handsome man, with quite a human countenance, and a rather slovenly costume, but with nothing particular in his manner or appearance, met us, gave us a cordial greeting, and proved to be (as I duly learnt by what took place) the philosopher. Oh, the relief it was to me to find he was like any other man! and, oh, the mystery that such an ordinary human being should be a philosopher! I forget his name, but I remember his silvery laugh and his chafing Dad about French soldiers being Scarlet Runners, and German sailors Prussian Blues, and English captains blushing Cucumbers, and a lot more nonsense that probably had point and piquancy when uttered, and remains with me only in a kind of fossil state, without form and void, and involved in darkness on the face of the deep.

You see, I am beating about the bush. The fact is, I remember many things about the philosopher better than I remember his garden. Now, strange to say, my numerous observations of gardens have helped me to some extent to recall, by an act of introspective comparison, many of the primary features of this garden. I remember some talk about collections; and it appears to me that the philosopher had collections of all the classes of plants he thought worth collecting. I seem now to hear him say, something in this fashion: "The man who makes collections of Potatoes, Peas, Parsley, and Pumpkins is a fool; but there is some sense, if you want intellectual amusement, in collecting species of Delphiniums, Dianthus, Drahos, Dodecatheons, and Droseras; but" (to sustain the alliteration) "collections of Dracoccephalums, Digitalis, and Dornicums would just suit an idiot's paradise." I remember that he talked considerably, and hammered away very much about the occupation of the garden with plants that, by usefulness or beauty, were really worth a cultivator's attention. "We must leave the weeds to Nature," he said; "they are beautiful in various degrees, but we must root them out of our gardens. If we want to see Thistles in perfection, let us not plant them in our gardens; rather let us go the country and ramble about and take our chance of finding them: if we do find them, we shall find good samples—better far than we can produce in our gardens." Now, it occurs to me that the philosopher explained to Dad the reason why our British plants usually fail in gardens, while exotics prosper—"a great enigma" he used to say. Now, this was his explanation: Exotics have no choice of conditions; they must live and die according to the conditions they are subject to when taken into cultivation. Those that are of an adaptable nature—as, for example, the zonate-leaved Pelargonium (the "Geranium" of that day)—and by their beauty compelling assiduous attention to their wants, are mastered by the cultivator and obtain a permanent place. Exotics must live or die, but natives will live in the field, though they may die in the garden. But why should they die in the garden? Because, in the first place, we do not value them sufficiently to ensure them the conditions they require; and, secondly, because many that we prize the most are the least adaptable to a variety of conditions. "Look at our native Orchids," I seem to hear him say; "if you plant them in the common border, and expect them to thrive in the same soil as the Primrose or the Pansy, you will probably lose them, and serve you right. If they had cost you a thousand pounds apiece, you would not grudge them a piece of chalk or something else needful. But the wise man will hunt for them on the downs and in the woods, and never tear up a root; for he will say, 'Let Nature grow these things for me in her inimitable style, while I grow things that Nature never would produce for me in this climate.' Thus," added the philosopher, "exotic plants are more worthy of our attention, because the natives do not need cultivating at all."

The Philosopher's Garden was not particularly gay or startling in its appearance. I know Dad was never tired of describing it as an "interesting" garden. At that time the bedding system was but partially developed, but green grass and clean gravel were well known, as were noble trees and lustrous evergreens. This garden, I know, was rich; for as I call it to mind I seem to be suddenly enclosed in groves and shrubberies that were vocal with a feathered choir. "No bird-murder here!" said the philosopher, when my Dad suggested that he might make a pasty of nightingales' tongues. There was ample space, breadth, dignity, and a conformableness of details to the primary idea. So at least I believe at this day, having in mind many good gardens that were much like, or altogether unlike, that of the philosopher. It was full of objects of interest, all more or less rustic or gardenesque. If in roaming about you came upon a good view, there was a rustic seat or alcove ready for your resting-place from whence to enjoy it. And there were retreats open to the south for chilly days, and others open to the north for burning days, and trees were usually employed to afford shelter; for the philosopher said, "There is no draught through a wood, and neither heat nor cold in a wood; therefore deep shrubberies must be the best shelter against sunshine, frost, and wind; and, as for rain, we should, weather permitting, imitate Lord Bacon, and take off our hats to it."

Two things especially made an impression on me. There was a snug rustic house in the garden called the "reading-room." It puzzled me to find a house with about half a dozen separate rooms in it called the reading-room; but I have a hazy kind of remembrance that, while the principal room was full of books and had comfortable lounging-places for readers, others were occupied with curiosities gathered from the garden, such as portions of trees perforated by beetles, great fungi that had been baked in the oven, wasps' nests; in fact, they were rough museums in which objects were selected and prepared for the grander museum within doors. One Watson Winnatt—so I remember the name, but perhaps incorrectly—was called to explain the things, and this disclosed to me the startling fact that the philosopher was either not acquainted with anything in the world, or was limited in his willingness to impart information.

An amusing five minutes may be spent in reading "Botany in a Bonnet Shop." The book is highly entertaining, and is one of those which one can take up and lay down at pleasure when the mind wants rest.

### THOUGHTS ON CURRENT TOPICS.

STILL "current," because it cannot be so soon forgotten, is the new year's greeting of an old and honoured correspondent, "D., Deal." Whether it was innate modesty, which so many admire who do not possess it, or merely a literary flourish to anticipate the public verdict

on his production would be "bad at the best," I know not; but this I know, it is not my verdict. On the contrary, I consider the greeting admirable, and when we remember it is the work—pleasurable work obviously—of a twenty-five-years regular contributor, it is, I think, little short of wonderful. Who amongst the younger scribes can hope to write so freshly after an intellectual drain of a quarter of a century? Instead of its being penned by the "oldest inhabitant," it might in some respects pass well as the happy effort of a writer just in the heyday of manhood. It is jaunty, agreeable, hopeful, and encouraging, and it contains a maxim that could only be born of experience—"Attempt what is possible, not what is impracticable, and don't get beyond your depth." To comment on that would be to weaken it. Let it be remembered, for it is not often that more wisdom is condensed in a line and a half. More power to the "old boy," good health, increased friendships, no woolly aphisms, and few floral failures during the current year.

TURNING over a leaf still new—we most of us pretend to do that at the beginning of a year—I find "B." writing sensibly on keeping Apples. He is right. The fruit will keep just as well in heaps as in the fashionable "single layers," if only sound examples be stored; even a good deal better buried like Potatoes than in too warm and too dry rooms. Tons of cider and culinary Apples are kept in this way as long as any others, and in the case of a few decaying the evil is not communicated quickly to others under these cool conditions. If it is desired to preserve a few choice late specimens as long as possible, wrap each in a few folds of tissue paper, then brown paper, and store in close boxes in a cold cellar. Do not use old newspaper, or the fruit may be flavoured with printer's ink, which is not always palatable either there or in "the press." Your correspondent is right on another point. Quantities of Apples and Pears are spoiled by being gathered too soon. It is much better to let them wait for a slight frost than to break them off the trees by twisting the stalks.

I AM obliged to Mr. Temple for recording his experience on the effects of tar in Peach houses, not because it confirms my suspicions, but because his evidence is more weighty than mine, and the lesson is enforced that it is dangerous to keep tar anywhere near ripening fruit. I am quite as willing to be opposed as sustained in anything advanced, for while endeavour is made not to write recklessly and without as much deliberation as can be afforded, a stray "thought" may need correction, and I earnestly hope may be corrected.

FOR instance, thinking quickly over the subject, I am impelled to say that the elaborate Potato experiments that have been conducted at Chiswick during the last two years, and recorded on page 5, are of no practical value—or rather perhaps it should be said the results are far from being commensurate with the labour, well and worthily as it has been applied. What are we told? That Potatoes not earthed produce several greened tubers. Did not all the gardeners in the land know that years ago? That bending down and consequently rupturing the stems of the plants reduced the weight of tubers. How could it be otherwise? Had the summer been wet instead of dry the experiment would have been ruinous. If the Special Committee make further experiments, let me suggest that they tie the stems of some plants up, so that all the leaves are fully exposed to the light and air, and break some of the others down. If they will do this, and the former do not yield a crop of tubers 20 per cent. better than the latter, I will engage to eat the lot if allowed and afforded time.

IN my opinion the "Jensenian system" of earthing Potatoes much deeper than is customary is incorrect as regards its origin, and the Royal Horticultural Society is engaged in the dignified occupation of nursing a philosopher's fad. As has been more than once published in this Journal, the system of repeatedly "moulding" or "crowning" the roots of Potatoes with earth has been practised on a ten times larger scale in this country and for a ten times longer period than in the Chiswick experiments, long before Professor Jensen's name was heard of in this country. Let no one imagine that I advance any claim to the authorship of the practice. I am, like the Chiswick experimenters, an imitator. I have tried it and found it answer in wet seasons, but should be as sorry to pretend it is the Thinkerian system as the Royal Horticultural Society would be to claim it as the Chiswickian. It is neither Thinkerian, Chiswickian, nor Jensenian if we go to the origin of the practice, as we should do for authorship. And where are we led? Among the savages. The system has been borrowed from the Aborigines of New Zealand. It is the established method of culture of the Maories, and if it is necessary to give it a scientific name the right one is the Maorian system. This is "one to the savages" in these days of advanced civilisation, and we may expect to see the "New Zealander on London Bridge" soon.

THE only conclusion having a practical bearing that appears to have been arrived at in the Chiswick experiments as regards extra earthing, is the probability that its effects differ in differing varieties. This may be so, but of what earthly use is the knowledge by the side of an equal probability of the results varying in differing seasons? During the cold wet summers of the last two decades the crowning method proved advantageous where it was adopted, but in the more favourable seasons of the past few years the returns did not compensate for the extra labour involved; and if the extra labour devoted to the rows at Chiswick were taken into account, as it ought to have been, the slightly increased value of the produce may have been purchased rather dearly. As no account

is rendered of the relative cost of the aboriginal Maorian with the old English method of culture, the results of the experiments under notice may be put down as *nil*.

So may those as regards the trial of whole and cut sets. Anyone who has had considerable experience in Potato culture can make the produce of the entire or divided sets preponderate according as they may be selected. It is the weight of the sets and strength of the issuing growths that govern, not the mere cutting or non-cutting of the "seed" tubers. No mention whatever is made of the weight of the sets in the experiments under notice, and that omission quite invalidates the authority of the summarised report. If the Council of the Royal Horticultural Society are really desirous of acquiring information that shall be of service to the nation, let a few varieties of Potatoes of established or prospective value for market purposes be planted in sets of different and ascertained weights of say, 2, 3, 4, and 6 ozs., their respective values being also recorded; also let them be planted at varying distances, and the results will show what weight, character, and value of sets can be the most profitably planted per acre. If a sub-committee determine that point, British farmers and gardeners may safely be left to choose methods of culture. Experiments conducted on some such lines as these would be vastly more useful than the practice of the past two years, as revealed in the "Summary of Results," read by Dr. Masters, and published on the page quoted. It is questionable if one cultivator out of a hundred could answer the important practical question indicated; indeed it is not unlikely if it were put to the accomplished Doctor himself, that he would have either to pause or search for a reply; is there not need, then, for authoritative information?

HAVING dwelt so long on Potatoes, in which everybody is interested I must skip a good deal; but not two contributions of Mr. T. Challis. His first on page 16 is, I think, one of the most able essays on the subject of the future of gardening and gardeners that has ever appeared. Wise counsel is therein conveyed to both masters and men, with a manifest desire that both may be benefited. This is the time of all others when master and servant should work together and have confidence in each other. The welfare of both is interbound, and neither can possibly gain if mistrust exists between them. Fighting for supposed "rights" may appear heroic, but there is this great danger of a false estimate being formed, and what are regarded as "rights" might possibly be sometimes more accurately described by another name. At any rate, it is well not to forget Abraham Lincoln's trite remark during a period of difficulty: "Never swap horses in crossing a stream."

MR. CHALLIS in doubting the forecasts of prophets becomes prophetic in turn in the following sentence:—"When by the passing of judicious land laws the owner and the occupier shall each feel himself safe to invest his capital with ample security, and with every confidence that it will be safe from the intrigues of misguided agitators—then, and not till then, will gardening and gardeners flourish with increased vigour." Numbers of landowners are arriving at the same conclusion, and that is the most hopeful sign of a better future.

I WISH we could feel the "National Gardeners' Relief Fund" scheme practicable; but there is reason to fear it is not. The number who would support it would be so limited that their contributions must consequently be greater than could be borne. The gardeners' benefit societies already established in Leeds and London, safe, sound, and excellent as they are, do not attract members in anything like such numbers that would justify the establishment of a "National Relief Fund." The capital would have to be very great to meet the strain of such times as the present. Only the larger trades, and hundreds of thousands of members, can support such an organisation. On that account vast numbers of workmen in towns, outside those trades, have formed loan societies, duly enrolled, and though these no doubt occasionally lead to indulgences, such as a seaside sojourn, they have been of enormous benefit in periods of adversity. And the rules are so framed that a Society of fifty members works as well as one having ten times that number, the payments in and out being in each case the same. I believe I could get some particulars of one of these societies if it were thought they could be of service to gardeners. I am not at all sanguine on the subject, but then when I had my "bumps examined" once I was told my "caution" was "very strongly developed," so had better leave the matter for the consideration of more enterprising persons.

BUT closely as I agree with Mr. Challis in the major part of the communication referred, I am compelled to differ very widely from him in his remarks on judging on page 28. His reasoning is excellent, but it is founded on error. There can be few, if any, "palpable and undoubted errors of judgment" unredressed if the two simple rules that are found in the schedules of many societies are adhered to, and competent judges are appointed. The rules are these:—"Complaints of exhibitors cannot be entertained unless made in writing to the Secretary before 3 P.M. of the day of the Show." Or any other convenient time may be stated, and the judges understand they have not completed their duties till after that time, but must be present to rectify with the Committee any possible oversights. The other rule is "the decision of the judges shall be final." Mr. Challis's experience of exhibitions and exhibitors may be greater than my own, but I think I know enough to assure me that if once committees arrogate to themselves the duty of altering the awards of their appointed adjudicators they open a door for

mischiefs that they will find a difficulty in closing again. They can grant "extra or consolation" prizes as they deem fit, but if they tamper with the judges' awards they will undoubtedly engender mistrust, and almost certainly make more mistakes than they will rectify. I could tell a few curious stories of committeemen and judges that would perhaps surprise Mr. Challis, and I strongly suspect would lead him to modify his opinions in some respects; but it is not necessary, for if those rules are provided and adhered to, and committees prove their competency in selecting able and experienced censors, "palpable and undoubted errors," however apparent to some persons, will, in ninety-nine cases out of a hundred, be reduced to mere imaginings.

HAS Mr. Challis read Dr. Johnson's famous work, "Rasselas?" If he has, perhaps some other Journal readers have not, and a passage may therefore be cited that is not without bearing on this subject:—"When in prospect of some good, whether natural or moral," observes the wise man, "we break the rules prescribed us, we withdraw from the direction of superior wisdom, and take all consequences upon ourselves. Man cannot so far know the consequences of causes and events as that he may venture to do wrong in order to do right. When we attempt to find a nearer way to good by overleaping the prescribed boundaries we cannot escape the consciousness of our fault; while if we miscarry the disappointment is irremediably embittered." The weight of those words will be admitted. The moment we break through rules and laws we are on dangerous ground, and that is why I cannot agree with your able and excellent correspondent on this question.

INTERESTING observations have been recorded on the handsome and useful Gros Colman Grape. Mr. Taylor is a thoughtful, observant, practical man, and everything he says on the subject is entitled to respect. The tendency of the foliage of this Vine to scorch he attributes mainly to a deficiency of potash in the soil. He may be right, but I have a strong suspicion that at least one great evil, easy to be remedied, is an inadequate supply of water. If the absence of potash alone is the predisposing cause of the premature collapse of the foliage, how is it that shaded leaves continue fresh the longer? They may be expected to be as well stored with mineral matter as the others, whether it be little or much.

THAT potash is essential to the well-being of Vines is proved by analysis. There is much of this in the wood and fruit, but very little in the bark. For the leaves I cannot answer satisfactorily. I have collected from time to time from various sources analytical tables showing the constituents of different parts of the Vine—wood, bark, leaves, manure, skins, stones, juice. Potash predominates in all except the bark and the leaves, and the latter contain more than four times the quantity of carbonate of lime than of potash. Why then cannot I answer for the leaves? Because I have no proof that those examined would not have contained more potash if it had been in the soil for them to appropriate.

PARDON a little digression. After a good deal of thought on the subject I have arrived at the conclusion that analytical tables giving the constituents of Vines, or anything else, are of little value, or, worse than that, may be misleading if unaccompanied with an analysis of the soil in which the products examined were grown. In four tables showing the constituents of the wood of Vines the quantity of potash varies greatly. Nor is this to be explained by chemists differing from each other in their work, because there are no greater differences than those found by the same chemist as the result of his examination of Vines grown in separate localities; there is the possibility, therefore, of being misled in this matter by strings of figures unless they refer to the soil as well to that which may be grown in it; still the fact remains that the leaves of Vines contain, so far as I know, a very small relative amount of potash. If any readers can show this is not so I shall be very much obliged to them.

BUT there is no doubt they consist chiefly of water. This is constantly escaping by evaporation, and if to a greater extent than is absorbed by the roots, there can be no other result than a collapse of the foliage. If shade is afforded evaporation is arrested, and the leaves remain fresh. The supply from the roots is then equal to the demand of the atmosphere. That demand being so great, and the moisture so readily yielded by this particular Vine, does it not seem reasonable that the root supply should be increased in proportion? I am convinced this is the root of the evil.

BUT why should Gros Colman possess what may be termed greater evaporating power than other Vines? There are two reasons. One of them anyone can see with the naked eye, the other possibly with the aid of a microscope. The obvious reason is this: The leaves of Gros Colman are not only large, but nearly entire; those of most other Vines both smaller and more or less divided. Contrast the leaves of Gros Colman with those of Muscat of Alexandria or Mrs. Pince for instance. Measure with great accuracy the superficies, and it will be found that the evaporating area of the former is much the greater; multiply the difference by the number of leaves on the Vines, and, if I mistake not, this will demonstrate that the variety under discussion needs distinctly more water than the others, and if it does not have it the foliage will fail by exhaustion.

THE other thought on this subject—the microscopical thought—is not my own; I am simply the recorder of it. In discussing this matter with a close botanical observer, who will soon know "who 'Thinker' is" (but that does not matter), he remarked that the cells are unusually separated

in the leaves of Gros Colman, and therefore moisture is quickly extracted by the sun. The closer the cells are packed together the greater is the resisting medium to the solar rays, and *vice versa*. Consequently the looser the tissue the greater the supply of water must be to sustain it, or shade must be afforded to arrest evaporation. For these reasons, then, I think that more water rather than more potash is required to enable Gros Colman to "keep its foliage;" but fortunately both can be given together if liquid manure, consisting largely of urine, be poured to the roots of the Vines. I will now cease thinking at present, and let others have a turn.—A THINKER.

### CAMPANULA CORONATA.

AMONG floral treasures the Campanulas hold a conspicuous place. Scarcely a country within the temperate zone which does not contribute several species to this very interesting genus. Their general appearance is well known, for the gardens are few indeed in which some Bellwort is not to be found. In so extensive a genus considerable differences of habit would naturally be looked for; and, accordingly, we find species varying from a few inches in length—as in the elegant little *C. pumila*—to several feet, as in the equally well-known *C. pyramidalis*. Some of

Fig. 10.—*Campanula coronata*.

them are trailers, of which class the *C. garganica*, often cultivated as a window plant, may be cited as an example; but far the greater portion of the species are of erect growth. A few are annual, and there are about twenty biennial species; but the genus consists chiefly of herbaceous perennials. White, and various shades of violet, blue, and purple, are the prevailing colours; there are, however, several yellow species, and also a few of a reddish lilac, but none of a distinct red tint.

The present plant is a hardy perennial, growing about 3 feet high, and having foliage closely resembling that of the Peach-leaved Campanula, *C. persicifolia*. The white calyx, with its green tips, has a very pretty effect, and we strongly recommend the species for general cultivation. It is of easy increase by seeds or division of the roots in spring.—W. T.

### HORTICULTURE IN THE UNITED STATES DURING THE LAST FIFTY YEARS.

THIS is a subject not unworthy of our consideration when we look at the almost universal interest it exercises over the minds of the people of the present day.

At the time our story begins, 1837, Philadelphia was considered the headquarters of horticulture; here were to be found the Landreths and

Maupays, as nurserymen, or dealers in fruit and ornamental trees; while Buist, Sherwood and Dryburg, Ritchie and Dick, McKenzie and Buchanan, with D. Feters, were florists of good repute, and the few private collections of any note were Pratt of Lemon Hill; J. B. Smith, of Moyamensing; General R. Patterson, and Mr. Pepper, the brewer, whose greenhouses occupied a building on Chestnut Street, second and third storeys.

The principal kinds of plants then in demand consisted of Camellias, Roses, Pelargoniums, and Chinese Primroses. Of hardwooded New Holland and Cape of Good Hope plants, were Acacias, Pimeleas, Chorozemas, and Leschenaultias, with a sparse sprinkling of Cactus, &c. Ferns were not known in those days by florists. In making up bouquets, which were not much in demand, the flowers used were mostly Camellias, Roses, single Chinese Primroses and Carnations, and as green to set these off, Chinese Arbor-Vitæ, with Rose Geranium leaves, were the steady standby. Plants in pots, for the decoration of private rooms or public halls, were seldom called for; in fact, the articles wanted, as Palms, Gum Elastic, &c., did not find a place with florists.

In New York, Thorburn, Hogg, Dunlap, and Bull were the leading flower growers, while as tree nurserymen, the Downings at Newburg and Wm. Prince, Flushing, were the only notable cultivators. Mr. Prince, though eccentric in character, was notable for his zeal in introducing new and valuable fruit and ornamental trees into the country, and among these new things, which, he it said, proved of little account, was the Chinese Yam, about which, for a time, he bored the country, but after giving it a fair trial it was found that half a day's work of a man was necessary to dig as many roots as would make him a dinner.

Boston then contained one horticultural establishment of merit, that of Hovey & Co.; one of the firm, C. M. Hovey, conducted the *Horticultural Magazine*, the only monthly periodical of the kind in the country. It was ably managed, and gave much valuable information on fruits, among which Mr. Hovey is an expert even at the present day. He it was who, against much opposition, advocated the merits of the Concord Grape, and it has nobly sustained the estimate he then formed of it. Boston people ought to be thankful that they have had a Hovey and a Wilder to educate them up to the high standard of horticulture which they now enjoy, and in which work my old friend, Dr. Asa Gray, has given valuable aid.

In the year 1837 such plants as are suitable for ribbon and carpet bedding out were almost unknown, but we then formed groups of Roses, double Dahlias, Heliotropes—mixed with Fish Geraniums, as they were then called—but the effect produced was anything but artistic. But about this time a scarlet, a white, and a lilac Verbena were introduced by me (not by R. Buist, as published), and florists, by crossing these, in a few years numerous varieties were raised of almost all shades of colour save yellow; and just let me say here, parenthetically, that I grew a yellow Verbena in Scotland in the year 1832 (*Verbena sulphurea*), introduced from South America by Dr. Gillis; unfortunately, it never has found its way into the United States, so far as I know.

A few years previous *Petunia phœnicia* had made its appearance, and by crossing this with *P. nictaginiflora*, a white species, many beautiful varieties, both single and double flowered, were the result. Now began fancy grouping of these, aided by the new varieties of fish or scarlet Geraniums of various shades of colour; but people were not contented with brilliant flowers; they sought after plants with gaudy foliage, which they found in Coleus, Achyrantbes, Alternantheras, and Centaureas; so, at the present day, it is no uncommon thing to find a bed filled with flowers and foliage of as many colours as that which made Jacob's coat so remarkable, and we would here remark that it takes no inconsiderable amount of taste to have the colours harmonise in arranging such beds, be the style either the ribbon, carpet, or mixed type. Ladies, as a general rule, excel in this kind of work.

In Baltimore, where the taste for floriculture of late years has made rapid strides, credit is due to the Feasts, the Pentlands, and the Hallidays for the aid they have rendered, while we think that the Maryland Horticultural Society, by its exhibitions, has exercised a more powerful influence than any other agent in bringing about the present pleasing state of things. Hundreds of florists have of very recent years sprung up in the city and its suburbs, yet these cannot supply all the demands for bridal parties, funerals, public feasts, and private parties, so that quantities have to be procured from the northern establishments.

Then look at our public parks and squares in the city. What kind of aspect do they now present during the summer months from what they were a few years ago? They are found bright and beautiful, fit emblems of an advanced state of civilisation.

About twenty years ago, one of the commissioners of the squares flanking the Washington monument asked me what ought to be done to improve those grass plats. I replied, Remove the unsightly railings, and adorn the surface with groups of shrubs and beds of flowers. His answer was: "Oh! that would never do, as people would pull them up root and branch." My answer to this was, Only give the thing a fair trial, and that it was his duty as a progressive man to educate and refine public taste.

In the same space of time that horticulture has advanced so rapidly pomologists have not been idle. The ancient list of native Grape Vines, which embraced little more than the Catawba, Isabella, and Lenoir, is now supplemented by new and superior kinds that would stand counting by the scores. From many, wines are made equal in bouquet to any foreign brand, thanks to the late N. Longworth, of Cincinnati, as the forerunner in this laudable enterprise. The State of Ohio gave us a J. P. Kirkland, who raised some of the finest Cherries now under cultivation.

Of Pears numerous sorts have been introduced from abroad, but among these, if we except the Bartlett, it will be found that the finest and most profitable sorts are of native origin, having sprung up in hedgerows and waste places, to which have been added some fine sorts by Mr. Clapp and Mr. Dana. We do not venture to say much about the notorious kind known as Kieffer; the last we ate were not very mellow, and the tree is not proof against blight as reported. Pears do not bring such high prices as they used to do, but that wholesome and desirable fruit, the Apple, still receives valuable additions to its number of kinds, and the quantity grown is immense. The quality of such as are grown in the Middle and Northern States does not compare well with those grown in the Western States in size and smoothness of skin, so that in the market the growers in the State of New York will scarcely be able to hold their own.

In the State of Delaware, and lands bordering both shores of the Chesapeake Bay, there are carloads of Peaches grown now for bushels that were raised fifty years ago, and the planting of new orchards still goes on, and will continue. Small fruits, as Raspberries, Blackberries, Currants, and Strawberries, have been greatly augmented in kinds as well as in quality. Every year brings forth a host of new Strawberries, some of them good in fact, while most are represented as better than the best, particularly should they be brought to your notice by a travelling tree charlatan.

By the foregoing meagre statement it will be found that the country has arrived at a high state of progress in horticulture, much of which is due to the writings of the Downings, Wilder, Barry, Meehan and many other noted men, combined with the work of the American Pomological Society; not forgetting the aid afforded by descriptive and illustrated catalogues spread broadcast over the length and breadth of the land by the almost innumerable nurserymen and florists found in every section of our diversified and fertile country.—W. D. BRACKENRIDGE (in the *American Farmer*).

### ODONTOGLOSSUM ROSSI MAJUS.

THIS is a useful cool house Orchid which ought to be grown in every collection. The flowers are freely produced from the side of the pseudo-bulb on a short stem about 6 or 7 inches high, which generally carries about three of its beautiful flowers. The flowers are suitable for cutting, either to fill small vases for bouquet or buttonholes. In colour the flowers vary slightly. The sepals and petals are white, heavily spotted in dark forms with purplish crimson. The lip is large and pure white, while all round the column some varieties are heavily spotted.

In addition to the value of the flowers in a cut state, the plants, if grown in small pots or pans, are effective for front rows in the conservatory, arranged amongst Grasses, Mosses, or small Ferns. For room-decoration it is also useful, and may be employed for a short time where gas is not used. For this purpose plants in 4-inch pots and pans are beautiful, with about half a dozen spikes of bloom. In rooms they are best suited for using singly in small vases, and not crowded with other plants. They should also have light positions, and never be allowed to suffer from an insufficient supply of water. It is not wise to allow the plants to remain in rooms more than a week or ten days. Care must be taken to stand them where draughts will not strike upon them, or against windows that are opened early in the morning.

This variety is particularly cheap just now, and imported plants may be purchased for 2s. 6d., while for double the price plants may be had with from twenty to thirty pseudo-bulbs. Such are certain to produce from three to six breaks. This variety is now within the reach of all, and those who want choice flowers in quantity should grow a good number of this lovely Orchid, for they can be had in perfection without occupying much stage room. In fact, if they are grown in small pans instead of pots they can be suspended from the roof of the house. They do well on blocks, but these give considerably more trouble in keeping them watered than when grown in either pots or shallow pans.

All intending to cultivate this Orchid should start with imported plants, and no time is more suitable for purchasing them than the present. If they are received at once in good condition and well cared for during the season of growth, they will develop pseudo-bulbs which will flower profusely next winter about this time. When the plants are received all dead and decaying, pseudo-bulbs should be removed and the fresh plump ones sponged before they are potted or placed upon blocks. The pans or pots must be liberally drained by half filling the pots or pans with potsherds or charcoal, or a mixture of both. If pots are employed they should be more than three parts filled with drainage, for they will then hold as much soil as the pans. When pans are to be used, those from 4 to 6 inches in diameter are the most suitable, unless a large size is required. We prefer pans to pots because the plants are naturally dwarf, and have a neater appearance when suspended from the roof than pots. After the pans have been drained place the plants in them in a mixture of fibry peat and charcoal. Shake out the soily particles of the peat before use, and then it can be preserved in good condition for at least two or three years, which would not be the case if the compost was intermixed with sphagnum moss, which decomposes in one season. In potting them the peat should be moderately well elevated above the rim of the pans or pots used, and the few old roots that the plants possess should be retained for the purpose of securing them firmly in the soil. They are rather more difficult to make secure than many Orchids, and if this cannot be satisfactorily performed, a few wire pegs may be employed, by which they can be held in position on the surface of the peat. Arrange evenly those pseudo-bulbs most likely to produce a break.

When the plants are placed upon blocks of wood, a little peat fibre or

living sphagnum moss should be employed under to retain moisture about them after rooting is commenced. Before this is done, drive four or six copper nails into the block, and when the plants are placed into position they should be made secure by means of copper wire. Then other wire should be fastened to the blocks by which they can be suspended from the roof. Arrange these so that the block hangs horizontally.

After the potting, the moisture of the house will be ample for ten days or a fortnight. During this time they will be better standing amongst other plants, or in a partially shaded position if any growths have started. Subsequently they can be lightly dewed with the syringe daily, and the pseudo-bulbs will soon become fresh and plump. When they reach this stage, keep them in an intermediate state for moisture until growth commences. As this advances more water may be given, and neither in summer nor winter must they be allowed an insufficient supply. They will bear watering over the foliage, and those on blocks may be liberally syringed twice daily during the season of growth. A surfacing of living sphagnum moss will assist in holding moisture about the plants.

During growth this Orchid should be shaded from bright sunshine, but dense shading must be avoided, or the foliage will become weakly. Admit air freely on all favourable occasions, as when the house is kept closed the atmosphere is liable to become saturated with moisture, and the young growths are certain to suffer if water lodges in them. The weather externally must guide the cultivator in syringing the plants.

Although this is considered a cool-house Orchid, the low temperature recommended by some is a great mistake, and should not be practised, or serious results will follow. Many have tried a low temperature for these plants to their cost, and have abandoned it for a warmer and more genial atmosphere. I have tried both systems, and the cold one cannot be too strongly condemned, for the plants, if they do not actually die, go back as much during the winter as they make progress during the season of growth. Perhaps *O. crispum* and *O. Pescatorei* will bear a lower temperature than any other *Odontoglossums*, but even then they do not increase half so rapidly as when grown warmer. A reliable and a safe night temperature during the winter, say from October until March, is 50° to 55°, the highest figures only being maintained during mild weather. During severe weather no harm will be done if the thermometer falls to 45° by morning on a few solitary occasions. The temperature, after the month given, is gradually increased as the season advances until artificial heat can be entirely dispensed with, which is generally the case early in June or some time during that month. The object during summer is to keep the plants as cool as possible, avoiding cold draughts on all occasions. Fire heat is again used in September, or as soon as the weather compels us to do so. Under moderately warm treatment more attention is needed in admitting air to insure a sturdy compact growth, which is certain to be obtained if the house is freely ventilated.

Up to the present time I have never seen an insect on our plants of *O. Rossi majus*, but they are liable to the attacks of aphides and yellow thrips. Both are easily destroyed by the use of weak tobacco water. The thrips, if very troublesome, are readily destroyed by dusting the young growths with tobacco powder, but care must be taken to wash it clean out of the growth again afterwards. These plants do not like being fumigated, and therefore we never practise it.—SCIENTIA.

### KITCHEN GARDEN.

**VACANT GROUND.**—In cases where labour is limited the vegetable quarters are cleared from time to time during the autumn and winter, but the soil is seldom dug roughly or trenched until planting or sowing time comes, when it is turned over in a hurry to get the crop in. This is by no means the best way of treating vegetable quarters, and those who follow this practice need not expect their crops to be first-rate. Good cultivation of the soil always pays, and although its advantages may not be much noticed in spring and as long as the weather is cool, but it is in the hot dry summer months, and when the crops are maturing, that the greatest benefits are derived from deep winter digging and trenching. All kinds of soils are improved by this, and particularly those inclined to be stiff. All vacant ground should be turned at once, and where there is a quantity of Broccoli, Savoys, and Brussels Sprouts taking up space that will be required for spring crops, dig them up with good balls of soil and lay them in close together in a spare corner. We always practise this plan. Of late we have had much frost, and we are delighted to notice the way it has pulverised the surface of some stiff soils which were dug in November.

**MANURING.**—This is closely connected with digging, as some are in the habit of applying manure at the same time as they dig. In some cases the practice is good, but not always. When the manure is well decayed we always use it at the time of sowing or planting, but when we have very rough material to deal with, we dig it in during the winter and a considerable time before the cropping season. Plants which root deeply, such as Carrots and Parsnips, should never come in contact with rough manure, and the ground for all such crops should be manured early; but for Onions and Cauliflowers the manure can hardly be too near the

surface, and the best way is to fork it in immediately before putting in the crop. This, however, should not be taken as a substitute for winter digging, as forking manure into the surface and turning the soil up from 12 inches to 20 inches are two different operations.

**LEeks.**—Those who desire to have large Leeks for show by mid-summer and early autumn must sow these at once. The young plants will not bear forcing, and are best in a greenhouse or frame temperature. The soil cannot be too rich for them so long as they have a few pieces of fibrous turf to take to. A high temperature produces the largest plants, but it is a most difficult matter to prevent their flowering prematurely, and large numbers are often lost in this way. The main crop of Leeks will soon be valuable. They are useful in February and March; and when fully grown, as they all are now, they keep well if lifted and laid in behind a north wall or hedge. When left in the open quarters they generally become very tough in April and May, but we have never noticed this with plants in the shade as suggested.

**SPINACH.**—It is a long time since winter Spinach was so scarce with us as it has been lately. Our culture was the same as in former years, but the hot dry weather experienced at the time of sowing and when the plants were young was rather too much for them. The roots are there, and they may grow freely when fine weather comes and will give us useful gatherings in spring. We shall not trust to this altogether, and some of the round-seeded sort will be sown at once. It will soon grow in a sunny sheltered position, and we advise all who may have been disappointed with their autumn-sown crop to sow at once. In April and May vegetables are often scarce, and a good breadth of Spinach is very serviceable.

**SPRING CABBAGE.**—These always pay for the best of attention. They cannot be too early or too abundant. So far they have grown well, and those planted about the end of August are now forming good heads; but it is those which turn in about the beginning of April and onwards which are the most useful. Where the plants which are being grown on for a supply at that time are not earthed-up sprinkle a small handful of guano round each, and then draw the soil firmly up to the stem. Any blanks in the rows should be made up before completing this operation, and where there are many plants in the seed bed plant out another batch.

**CAULIFLOWER.**—Autumn-sown plants which are being wintered in frames and under handlights are looking well, and if properly managed they should not deteriorate now. Avoid putting any dark covering over them unless it is absolutely necessary. When they are covered at night from frost, always take this off during the day, and admit air freely on all favourable days. This treatment will produce very dwarf dark green-leaved plants, and these usually succeed well in spring. Make a first sowing of anybody's extra early under glass. A great many plants may be raised in two or three 6-inch pots, or the seed may be sown in cutting-boxes. Do not use sand in the soil, but sow in a mixture of loam and well-decayed manure. The latter should be used rather sparingly. As soon as the plants appear keep them fully in the light and near the glass. Do not put them into a temperature above 60°.

**LEAF SOIL.**—This is excellent for many vegetable crops, and where pits are being cleared to be refilled in spring save all the decayed matter and put it under cover to keep it dry and ready for use. When the drills are opened for the reception of seed Potatoes, if a quantity of this is put down where each set is to be, and more on the top of the tuber, the Potatoes will turn out beautiful and clean. In heavy soils leaf soil may be used with advantage for all crops; sand and old potting shed soil are also excellent for covering seeds in early spring, and now is the time to see that a stock is in readiness for use during February and March.

**HORSE RADISH.**—It is a mistake to dig and replant this annually, but it spreads so much that it ought to be taken up every two or three years and either put in a fresh place or restricted to the old. This may be done now. The ground in which it is growing should be trenched, and in doing so pick every one of the roots out. Select some of the thickest and straightest for replanting, and cut them about 6 inches in length before putting them in. The soil in which they are replanted should be rich and deep, 2½ feet from row to row, and 15 inches from plant to plant will be found a good distance to plant. We dig the ground first, and then dibble in the roots afterwards, and the whole of the roots which are left are laid under soil or ashes for use as required. We always grow our Horseradish in rows between fruit bushes, and it has no chance of taking possession of vegetable quarters or disturbing any other crop of value.

#### FRUIT FORCING.

**MELONS.**—Seeds having been sown as advised the plants will now have formed the second or rough leaves, and as the root-action will be in proportion to the increased growth, the necessity for the removal of the plants into pots a couple of inches larger in diameter will become apparent. This must be done before the plants become root-bound, again plunging them in a bottom heat of 75° to 80° and near the glass, putting a small stick to each plant for its support until large enough for transferring to the hillocks in the Melon house. Plants that are intended to be planted in pits and frames, and trained over the surface of the beds, can be planted out as soon as they require more room at the roots.

**Soil.**—The Melon requires good turfy loam, preferably heavy than light, which has been cut and stacked in the previous autumn. The top 3 inches of a pasture grazed by sheep is best, and as a rule loam of this description without anything else is ample for the production of high quality fruit, but we add about a sixth of old mortar rubbish, and find we get a shorter-jointed growth, better textured foliage, and more fruitful plants, with heavier fruits. If the loam be poor add a fourth of thoroughly decomposed manure free from worms. A quart of soot to each bushel of

compost may be added with advantage, and under any circumstances is beneficial. It should be under cover a few days to dry, be chopped moderately small, and turned twice to become thoroughly mixed.

**Planting.**—Cleanse the house or pit thoroughly, the woodwork with soft soap and hot water, the glass both inside and out with water only, and the brickwork with hot lime. Make a hillock in the centre of each light by putting in a barrowful of soil, flattening the top, which should be about 9 inches from the glass, and not more than 1 foot, the depth of soil in the centre of the hillock being 10 inches. The soil having been in the pit or frame a few days to get warm, a plant may be turned out in the centre of each hillock, or if the lights are large two plants, which is preferred by some for early Melons, but we elect to have but one plant in a light. In planting, press the soil firmly around each plant, be careful not to injure the stems or decay will soon destroy the plants. The soil at the roots should be moderately moist when turned out of the pots, so as to prevent the need of water at planting. A circle of quicklime may be drawn around each plant to keep slugs away and absorb moisture.

When the plants have made a couple of rough leaves pinch out the points of the shoots just above the second rough leaf. Maintain a steady bottom heat of 80° to 85°, or, if from hot-water pipes, 75° to 80°, as when the heat is had from fermenting materials it must necessarily be high at the commencement; and the day temperature 70° to 75°, advancing 5° to 10° from sun heat; the night temperature 65° to 70°.

**CUCUMBERS.**—*Winter Fruiter.*—Plants which have been producing fruit all the winter now exhibit signs of exhaustion, and will be the better for having the surface soil of the bed removed, and fresh supplied with an admixture of three parts loam and one of decayed manure and leaf soil, with about a quart of wood ashes in each bushel. This surface dressing will have an invigorating and beneficial effect upon the plants by encouraging active surface roots, and when these are had the plants will be in a position to take copious supplies of liquid manure.

*Regulating the Growths.*—Keep the young growths tied to the trellis, but not too tight, always leaving room for swelling; cut out exhausted growths and tie in young shoots so as to maintain a succession of bearing wood, and consequently of fruit. Avoid overcrowding the shoots, giving each space for development, and the foliage full exposure to light, and above all avoid overcropping as the greatest of evils.

*Young Plants.*—Shift these as they require more room; keep them near the glass till ready to plant for trellis training, putting a stick to each plant for support. The soil should be similar to that advised for Melons, and in the same proportions, adding a little charcoal to keep the whole porous, and made into ridges or hillocks. The treatment holds good with plants intended to fruit in pits or frames, stopping the plants at the second or third leaf. The temperature top and bottom should be the same as advised for Melons.

**VINES.**—*Earliest House.*—If the inside borders have not been watered since the Vines were started they should have a good supply at a temperature of 80° to 85° as soon as the thinning has been brought to a close, or if the borders are at all dry a good watering may be given before the flowers open, when a rather dry condition of the atmosphere must be maintained, with a night temperature of 65° to 70°, and 70° to 75° by day artificially. The covering outside should also have attention, and if fermenting materials are used a temperature of 80° must be kept up by means of additions and frequent turnings. Proceed with tying and stopping young growths until the foundation of an even spread of foliage over every part of the trellis has been secured. Select the most compact bunches for the crop, fertilise all shy-setting varieties with Black Hamburgh pollen as soon as they come into flower. Thin the most forward bunches of Black Hamburgs first, deferring the bad setters until it can be seen which are the properly fertilised berries. We may mention Madresfield Court as decidedly the best Grape we know with a Muscat flavour for early or mid-season work.

*Second House.*—Syringe two or three times a day, and turn the fermenting materials frequently, alike to prevent overheating and to liberate moisture and ammonia. Discontinue syringing when the bunches become prominent, but keep up atmospheric moisture by damping the paths and walls two or three times a day until they come into flower, when a free circulation of air rather dry with a little more fire heat will facilitate the setting process.

*Vines in Pots.*—Fruiting Vines must be carefully attended to, giving tepid liquid manure a few degrees warmer than the house, adding a little fresh top-dressing when the roots appear on the surface, and thin early, guarding against overcropping. Cut-back Vines intended for growing into fruiters may be taken into heat for starting, and when they have made 2 or 3 inches of growth shake out and repot them in rough rich compost, using pots 6 to 9 inches in diameter, according to the roots; plunge them, if possible, in a mild bottom heat, and keep them near the glass, so as to insure short-jointed growth and thick leathery foliage.

*Stored Grapes.*—Look over these frequently. Dispense with fire heat as much as possible, a temperature of 40° to 45° being sufficient; maintain it as equable as possible, keeping the shutters closed to effect that and reduce the need of fire heat. Admit sufficient air to prevent an accumulation of damp, and keep the bottles or troughs filled with clear rain water.

#### PLANT HOUSES.

**Dracænas.**—The root stems of these plants that were placed in pans in autumn will now be ready for transferring singly into 3-inch pots. After potting, plunge them in bottom heat of 75° to 80°, and in a short time they will be established and rooting freely in the new soil provided they can be kept in a night temperature of about 65°. These plants will

do well in a compost of fibry loam and about one-third of peat, leaf mould, and coarse sand. Plants that have been in rooms and similar positions may, if they have been kept dry for a few weeks, have the root portion of the stem cut into lengths and placed in pans in a compost of light sandy soil. If these are given the temperature indicated above they will quickly start into growth. *Dracaena rutilans* is invaluable for decoration in rooms, and a good number of young plants may be raised at once and grown in a moderately warm temperature, so that they can be topped and re-rooted later in the season, for with large bold leaves at the base they are more handsome for decoration in single vases than when raised from portions of stem. Plants raised by the latter means have always small leaves towards the bottom. Any plants of *D. gracilis* or *D. Goldiana* that have grown too tall for use may now be cut down and the heads rooted. These should be cut off where the wood is moderately soft, and they will root in much less time than if cut where the wood is firm. The heads may be placed in 4 or 5-inch pots with a little sand at the base. These may be well watered and plunged in the bottom heat advised above; if covered with a handglass and kept close they will root without losing a single leaf. If an increase in the stock of these is desired they should be kept in heat until they break into growth, when the shoots can be taken off and rooted.

*Plumbago rosea*.—This and *P. coccinea* as they cease flowering can be cut back and thoroughly cleaned before placing them in heat. While in flower they are very liable to become infested on the under side of the leaves with thrips, and the plants must be dipped in tobacco water. If this is done and the stools are placed in brisk heat they will produce clean cuttings that with ordinary care will become useful plants for another year.

*Linum trigynum*.—Plants of this useful *Linum* that have flowered should be cut back and introduced into brisk moist heat to induce them to start fresh growth. They are very liable to be attacked by red spider, and if this be once established on the plants in their early stages it will prove a source of annoyance the whole season. Frequently the cuttings are attacked before they are rooted, but this need not be the case if every old leaf is removed when the plants are pruned. If this is done and the stems of the plants dipped into a strong solution of some insecticide the cuttings can be taken, rooted, and grown for a time in a moist intermediate temperature.

*Poinsettias* and *Euphorbias*.—Keep those that have flowered in a temperature that will not fall below 50°, where they will rest completely. While there the *Poinsettias* must be dry at their roots, and the *Euphorbias* only have sufficient water to keep the wood from shrivelling. Many *Euphorbias* after flowering are lost by being kept too wet at their roots.

*Clerodendron fallax*.—Seed ripened in autumn may be sown in moderately light sandy soil in 6-inch pots. Plants so raised will be useful for flowering in 5 and 6-inch pots for conservatory decoration. Those who rely upon old plants may prune back a few that have had a good rest and place them in brisk moist heat. As soon as signs of growth are observed they may be turned out of their pots, the roots partially reduced, and repotted in a compost of loam, one-seventh of decayed manure, and sand. Water must be carefully applied for a time after potting until the roots are active.

*Begonias*.—Such varieties as *B. nitida*, *B. n. rosea*, *B. semperflorens*, *B. s. rosea*, *B. s. carminea*, *B. Ingrami*, and others that have been kept in small pots during the winter, may now be placed into 5-inch pots. Employ a compost of loam, one-third of leaf mould, manure, and sand, and grow them in a temperature of about 60°. If allowed to come into flower they will prove invaluable for the stove or intermediate structures during the spring months when those have become tall that have been flowering during the autumn and winter. A little seed of *B. semperflorens* may be sown on fine soil in a pan.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

*Hotbeds for Propagating Purposes*.—Hotbeds are by no means indispensable to propagators, but on the whole are preferable to any more dry heat, especially for raising plants from seeds. The best materials for forming into hotbeds are well-prepared stable manure and leaves in equal proportions, spent tan, or this and leaves, and spent hops. The first-mentioned must not be used fresh from the stables, but ought to be first thrown into a large heap, being turned inside out before the centre is heated dry, and again allowed to ferment for at least one week, when, if found to be only moderately hot, it may at once be mixed with the leaves and made into a hotbed, preferably in a forcing house of some kind. When stable manure only is used, it will sometimes be advisable to turn it a third time, and also before heated dry in the centre, as when the bed is formed too quickly a violent sour heat is generated, this being most injurious to plant life, and, besides, the centre of the bed soon becomes perfectly dry, and consequently gives off no heat. The manure from a cow yard is slow in heating, and is very apt to become suddenly violently hot. When well prepared a bed formed wholly or principally of this material is very sweet and lasting. Tan is also slow in heating, but this may be quickened by the addition of quicklime, say about six bushels to a waggon-load of tan, and this when well mixed with the tan also appears to check the spread of the fungus that usually renders tan so objectionable for heating purposes. Spent hops are apt to become excessively hot, and this must be prevented as much as possible, or much mischief may quickly be worked. Rather shallow beds should be formed, and a little fresh material added occasionally. When frames are stood on hotbeds these should not be kept closed till the heat has subsided somewhat and has become perfectly sweet, or otherwise cuttings may be destroyed wholesale, and seedlings damp off by hundreds.

*Pelargonium* and *Propagating Boxes*.—During bad weather the stock of these ought to be overhauled and repaired where necessary. The bottoms are the first to fail, and these would last much longer if each were provided with two narrow and fairly stout crosspieces, these keeping the bottoms off the ground, therefore more dry. When the bottoms are badly decayed it sometimes pays to completely reverse them, the top edges being strong enough to have the boards to form the bottoms nailed to them. A certain number of new ones are required every season, and these also ought to be made now. Large clumsy boxes are neither durable or at all handy; neither as a rule do plants thrive so well in them as they do in boxes about 4 inches deep. Most of ours are 24 inches long, 15 inches wide and 4 inches deep, but for *Alternantheras* we prefer to have them 3 inches deep. Nearly all plants transplant most readily from shallow boxes, in which little or no drainage beyond rough leaf soil or old Mushroom bed refuse is used. Where large numbers of softwooded bedding plants, such as *Heliotropes*, *Verbenas*, *Ageratums*, *Iresines*, *Lobelias*, *Konigas*, *Fuchsias*, *Petunias*, and *Marguerites* are required, small or ordinary propagating frames are of little avail, and large deep boxes covered with squares of glass are far more expeditious. Ours are 24 inches long, 15 inches wide, and 6 inches deep, about half the depth being filled with drainage and fine sandy compost, and this leaves sufficient depth for the cuttings without touching the glass, two squares of the latter covering each box. When these are filled and stood on a moist hotbed it is usually necessary to turn or else dry the glasses every morning, or too much moisture accumulates and damping commences. When the boxes are stood on dry beds, staging, or walks, the squares may well have all their edges covered with strips of paper previously pasted over, and these being fixed to both the glass and boxes render the cuttings nearly or quite airtight, and if shaded carefully they strike in a few days.

*Stock Plants*.—In order to secure a good supply of cuttings it may be necessary to at once place the stock plants of *Ageratums*, *Heliotropes*, *Petunias*, *Fuchsias*, and *Zonal Pelargoniums*, more especially *Golden*, *Silver*, and *Bronze* varieties, into a brisk growing temperature, maintained, say, from 60° to 65° by day, and rather less at night, and this should encourage them to break strongly. If the tops are not very hard these may be taken off and struck, but as a rule the young growth strikes most quickly, and continues to make the best progress. A dry atmosphere—that is to say, an overdose of fire heat, is most injurious to the stock plants, this encouraging spindly growth as well as the spread of insect pests, and it is almost needless to add that unless the cuttings are clean they will never become healthy plants. The cuttings being healthy and strong they strike quickly, and in their turn afford first one cutting or top, and several later on. Dwarf *Lobelias* are frequently propagated from cuttings, but it is a mistake to place the stock plants in a strong heat, as this induces the formation of puny shoots, and which are very apt to flower instead of rooting. When the plants are kept in a greenhouse temperature the cuttings are strong, and these strike readily in heat and soon grow into good plants. Where a good number of stocky old plants have been wintered in boxes as we have previously advised, these, if properly attended to and not forced, emit roots from the growths above the soil, and before these roots perish the plants should be pulled to pieces, every little division, when dibbled off thickly in boxes of good fine soil and placed in a gentle heat, soon rooting freely, and before bedding-out time attain a large size. As a rule *Coleuses*, *Iresines*, and *Alternantheras* can be propagated in sufficient quantities after the bulk of harder kinds, including those above enumerated, are cleared out from the forcing and propagating houses or places. Where, however, the stock plants are few in number, striking must be commenced at once in order that the old plants should produce more cuttings as soon as possible, the newly struck plants also yielding their quota. Tops of *Zonal Pelargoniums* of all sorts when taken from plants growing in cold houses or pits do not strike satisfactorily, but after the old plants have been placed in an early vinery or other warm house for a few weeks, say from a month to six weeks, the tops can be safely propagated. These strike better in pots than in boxes.

## THE BEE-KEEPER.

### DRONES AND DRONE COMB.

WHILE I fully recognise the usefulness of drones under various circumstances and states of the hive, it is not because I consider them to be absolutely necessary for other purposes unless to fertilise the young queens; on the other hand many hives are ruined by having an excess of drones and drone comb. It is therefore an important matter for the bee-keeper to know the number of drones necessary to a hive, but it is still more important to know how to regulate that number. In one case a hive may be rendered unprofitable by having 5000 drones, while another would not be affected by double that number: ergo a hive with less than from 65,000 to 70,000 worker cells to be occupied by brood only is too small if a portion of that be drone comb. Therefore a hive to be profitable must have that number of worker

cells irrespective of other worker cells for honey, water, and pollen, at the very least one-third of that number more.

Any amount of drone comb over that in a full-sized hive (provided it is outside the breeding worker combs) will not affect the hive injuriously; but all drone comb, particularly if in the centre of the hive of less dimensions than the above, renders such hive or hives unprofitable. A little thought and calculation should convince anyone that hives containing fewer frames than eighteen of the standard size are too small for practical and profitable work. Bear in mind that a prolific queen can lay 3000 eggs and even more daily, and hives of less capacity than stated above are too small and should be enlarged. By using proper-sized hives it lessens considerably labour in the apiary and adds materially to the profit. One of the great advantages claimed for reversible frames is that by reversing them more breeding space is acquired; proving the system defective, because in full-sized hives no such manipulation is necessary, thereby saving the bees labour in changing the position of the honey and inclination of the cells, as well as the wear and tear of their bodies in doing so, losing valuable time and lessening the harvest of honey.

Provision should always be made the previous summer to have all hives filled with worker comb to the proper quantity necessary for the profitable working of the apiary the following summer. Young queens as a rule perform that work satisfactorily, while old ones do the reverse. Hives with moveable combs admit the regulating the different combs in proper proportions. The straw hive precludes this, but we attain our purpose with them by placing a young queen at the head of a powerful swarm. If I find in the autumnal inspection an excess of drone comb it is pruned out and the bees fed to fill the space. With frame hives having a superabundance of drone combs in the spring it is better to sacrifice one or more hives if healthy, taking their worker comb and putting it in the place of the drone comb removed. The bees of these robbed hives will be profitably used in raising queens, and the queen put to a hive after swarming will make up for any loss sustained by the manipulation, which many bee-keepers might think unnecessary, believing that sheets of comb foundation would serve the purpose without sacrificing any hives. But foundation is not to be always depended upon. Frequently it is transformed into drone comb, and in the centre of the hive too. I am in receipt of a letter from a gentleman, a reader of this Journal, who says he tried brood-spreading last year, and two sheets of foundation he put in the centre of the hive were transformed into drone comb, which rendered the hive useless for the season. The above is not an isolated case. Had that hive been of sufficient size, and the drone comb been on the outside of the others, the result would have been very different. But again, drones raised in the centre of a fairly strong stock may be reckoned on as more vigorous, and are better adapted for successful fertilisation and producing bees strong in constitution. One or more hives should be kept for that purpose, and if early, as it or they should be, the drone comb after the first hatching might be removed to outside and worker comb substituted.

Although I have proved long since that drones issuing from the eggs of a fertile worker or unfertilised queen are perfect and capable of fertilising queens, still I am convinced that highly bred drones produce the best results in the progeny of the queens fertilised by them. Just as attention is paid the rearing of well-matured drones and the suppression of all others, will the vigour of the future workers be kept up, as well as that of the queen in her duties. With a prolific and vigorous queen there is a less desire in the workers to build an excess of drone comb. The desire to do so arises only when the queen is weak or incapable of fulfilling her maternal duties. Some people affirm that drone comb is built specially as store combs. I cannot accept that opinion, because where young fertile queens are, in the height of the greatest glut, few if any drone combs are built. It is

only when queens are aged or some way defective that this occurs. Not only are honeycombs prettier when of worker comb, but the honey in them is often less watery than that in drone comb. But in view of the biggest profit with the least amount of labour and disappointment the bee-keeper must study to keep hives of proper dimensions with drone comb in its proper place and of the right quantity.—A LANARKSHIRE BEE-KEEPER.

### EDUCATION IN BEE-KEEPING.

In an interesting article this subject was, a few weeks ago, discussed at some length by "A Surreyshire Bee-keeper." Several, however, of the views expressed are in such direct antagonism to those held by many apiarians that it is impossible for me to desist—since no other writer has taken up the question—from considering at length some of the opinions expressed and statements made in the article to which I have referred. It is indeed in no spirit of carping criticism that I write, but rather with the honest endeavour to bring out the views of probably a large section of bee-keepers, and by contrasting them with the views of "A Surreyshire Bee-keeper" and others of his way of thinking make bee-keepers, by reading both sides of the question and duly considering all the points which need attention, to form good and sound opinions upon the matters under discussion. "A Surreyshire Bee-keeper" regrets that bee-keeping is not one of the subjects taught in elementary schools; but is it not very questionable if any benefit would accrue to apiculture even if the Government would allow the subject to be included, which at present it declines to do? If bee-keeping—the production and sale of honey and wax—was to be a means of actual bread-getting, if from it the average man could gain an income sufficient to maintain himself and his family with certainty year by year, the advisability of apiculture being taught in schools would be at once apparent. I am not, however, sanguine enough as to the profits of bee-keeping, at any rate in the future, to encourage any such feeling, but rather desire to teach dwellers in the country districts to consider bee-keeping as an interesting amusement, a pleasant relaxation from daily routine toil, attended with moral, pecuniary, and physical profit than an industry upon which man may safely depend for affording an income sufficient to meet his various wants and requirements. Again, by the introduction of the subject into schools, would it not be the majority of children be called "lessons," and therefore to be avoided whenever possible? A large per-centage of the minority taking an interest in the art would gain a theoretical knowledge which might be of some practical value, but would most certainly have been learned with more pleasure and greater ease when school days were over and the mind enlarged by ordinary teaching is capable of grasping with greater particularity and ease the fundamental truths which must necessarily be learned by all who desire to make bee-keeping a pleasurable study or profitable undertaking. Bee-keepers are born, not made; the seed is there and only requires favourable conditions to cause it to germinate and in due time bear fruit. Associations, articles in papers, and neighbouring apiaries afford these necessary conditions, and produce far more satisfactory results than all the school teaching of years could, in my opinion, hope to effect.

I would now notice in passing the value of the various shows held in many parts of the country, which if conducted properly may indeed be valuable aids to the spreading of knowledge, but not if the result of, say, driving a stock in the presence of a wondering multitude who expect to see the operation performed alike easily and well, is the loss of many bees, owing to some unfavourable influence of the weather or a careless operator who, also by way of encouraging novices, receives a good many stings in the face, which even as he twitches from their effects he denies having received. Why should not a veil be worn? thus showing the absolute impunity with which the operation may be performed by even an unskilled manipulator. If the man driving could be sure of not receiving a sting he can dispense with the veil, but if there is any doubt far better to wear one than discourage those anxious to learn by being attacked and unable to defend himself against an angry swarm of bees. The least want of care at a show gives rise to feelings of distrust and undoes all the good done by previous efforts. Next the following sentence occurs, "No one who thoroughly understands practical bee-keeping can fail to pass for the third-class certificate. All that is required of the candidate is to show his knowledge of manipulation and as much theory," &c. What is practical bee-keeping? Surely, not only showing ability to manipulate, but rather by putting theory and knowledge into practice, gaining profit. Here is the difficulty, for there are many bee-keepers who cannot manipulate a bar hive

who can yet make a considerable profit, and there are also many who can manipulate to any extent and yet who cannot make a profit. Let me quote Professor Root, who in the *American Bee Journal* for 30th December last, says, "Then comes the question of manipulation . . . there is, again, spring manipulation, spreading the brood, and the like. In my opinion we have manipulated many a colony to death. I am getting to think less and less of manipulation."

Now, what I would suggest is that a candidate for the third-class certificate should, for one season at least immediately preceding his examination, keep a diary, authenticated by two respectable neighbouring bee-keepers, in which he should give all points of interest in his management, the value of his stock in the preceding autumn, the amount of food and its value given in spring, time spent in manipulation, weight and form of honey taken from each stock, current expenses, and nett profit after the value of the stock has been brought up at least to the level of the preceding autumn. Then, if after taking into consideration his district and the season, the weight and quality of honey is insufficient or too poor to prove him a capable apiarian, or if on the face of his diary any glaring want of judgment is seen that even if he passes his examination—until he is able by future success to show his ability not only to manipulate but to gain a fair weight of good quality honey from his stocks, thus showing that with increased knowledge of handling his bees he has not neglected to learn how to act so as to gain the greatest profit from putting this ability, knowledge, and theory into practice—the certificate should be withheld. So in each succeeding examination no certificate should be granted without this proof of ability.

Who does not know the man who can "do anything with his bees" but—get a great amount of honey? He is almost proverbial. May we hope that the tendency of the age is to revert to simplicity, to discard many operations now regarded as necessary, and by economy and increased knowledge of the habits of bees, combined with improved methods, enable English bee-keepers to hold their own in the race against the colonies and America, and to produce more cheaply, in greater quantity, and to sell at prices so low that honey will be considered not a luxury for the rich alone, but rather a necessary article of diet; the use of honey being by this means so extended as to counterbalance the lowering prices forced upon us by foreign competition and by the small demand for pure honey and wax at present existing.

These are considerations which have great weight with those who have the interests of bee-keepers at heart, and each one of us is striving to do his utmost for the industry; the means differ, but all are going forward to the same good end. Out of diversity of opinion benefit often springs, and by discussion valuable results may be attained which will fully compensate for all the trouble and labour necessarily attendant upon our endeavours, and if indeed no ill feeling be engendered it will be no matter of regret that the subject has been discussed, but rather for congratulation.—FELIX.

### BEES ABANDONING A HIVE.

I PLACED a swarm in a straw skep in June, and put it in my garden in a spot well sheltered by a Yew hedge. Here it remained, "apparently doing well," until the end of September, when I moved it to another garden about 300 yards off. I placed it on a raised board with a southern aspect and sheltered by a Thorn hedge. Yesterday (January 16th) I discovered the bees had forsaken, and on further examination found that the hive was full of comb, which latter contained a fair amount of honey; but as for the bees, all that remained of what had once been a very strong swarm was a dozen or so dead ones. Can you help me through your bee correspondents to account for this? It cannot have been wasps, or no honey would have been left. My gardener noticed the bees very busy going in and out of this hive a week or two ago, so it cannot have been empty long.—PLUS.

### TRADE CATALOGUES RECEIVED.

Edmund Philip Dixon, Hull.—*Catalogue of Garden and Farm Seeds for 1886.*

Richard Smith & Co., Worcester.—*Catalogue of Garden and Flower Seeds for 1886.*

Ant. Roozen & Son, Overveen, Haarlem, Holland.—*Catalogue of Bulbs and Roots.*

W. Cutbush & Son, Highgate, London.—*Spring Catalogue for 1886.*

James Cocker & Sons, Aberdeen.—*Catalogue of Vegetable and Flower Seeds.*

Sutton & Sons, Reading.—*List of Novelties.*

Robert H. Poynter, Taunton.—*List of New Chrysanthemums and Seed List for 1886.*

Samuel Yates, 16, and 18, Old Millgate, Manchester.—*Catalogue of Vegetable and Flower Seeds.*

Richard Dean, Ranelagh Road, Ealing, London, W.—*Catalogue of New and Choice Potatoes, and List of Vegetable and Flower Seeds.*

Little & Ballantine, Carlisle.—*Catalogue of Garden and Farm Seeds for 1886.*

P. J. Kane, Kells, Meath.—*Amateurs' Annual Seed List for 1886.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. B.).—The address you require is Mr. Thomas Sharpe, Royal Strawberry Gardens, Knowle Hill, Chertsey.

Manure (Young Gardener).—We will endeavour to obtain the particulars you require from our correspondent and reply to your letter in a future issue.

Tan Ashes as Manure (W. S.).—The ashes of tan contain potash, as do the ashes of all vegetable substances, also a small proportion of lime, and as such are useful as a dressing to land to be laid down to grass, having a particularly invigorating effect on Clover. Applied to grass they are very effective in destroying moss, and improve the herbage considerably. The ashes are likely to prove useful to fruit trees, especially Vines, a peck per rod, 30½ square yards, being a sufficient dressing at one time or annually, applying in early spring.

Marechal Niel Rose—Leaves Blackened (John Burn).—The black deposit on the leaves is caused by the plant being infested with some insect, we think scale, though we fail to detect any on the leaves or petioles. The insect is probably on the wood. You could not have a better remedy than softsoap and hot water—a solution of 3 ozs. of soap to the gallon of water, applied at 140° with a syringe. The scale has in all probability come from the Peach tree, which should be cleansed in a similar manner before the buds commence swelling.

Seedling Fern (A. D. S. K.).—The fronds sent are quite distinct from any we have seen if they show the true fixed character of the seedling. We have seen a form similar in the shape and size of the pinnules, but not with fronds so strong in growth and so much divided. It is likely to prove a useful Fern, and we advise you to exhibit a plant at one of the meetings of the Royal Horticultural Society at South Kensington. We will, however, endeavour to compare it with other Ferns of the same type and will give you our opinion in another issue.

Prices of Mushrooms (Profit).—The prices to which you refer are paid to the growers, and necessarily fluctuate according to the supply and quality of the produce. Higher prices are often obtained for Mushrooms in provincial markets than in London, because great quantities of Mushrooms are bought at Covent Garden and sent to the markets of provincial cities and towns. Mushroom-growing pays those persons well who have the proper materials at command and make themselves competent in the work—producing heavy crops from, say, the middle of October till the end of May.

Fuchsias for Bedding (F. J.).—Single varieties are the best for bedding. Dark varieties.—Charming, Wave of Life, Try Me O! Crown Prince of Prussia, Enoch Arden, and Beauty of Kent. Light.—Blushing Bride, Annie, Marginata, Minnie Banks, Erecta Von Novelty, and Beauty of Swanley. For bedding purposes the plants should be well pinched so as to form a dwarf bushy growth, and had strong before planting-out time—the end of May or beginning of June, hardening them well off. The last pinching should take place as soon as the plants become established in the beds, or about the middle of June, in order to have a fine display in August onwards till the occurrence of frost.

Good Pelargoniums (Idem).—Twelve single Zonal Pelargoniums are Ajax, Mrs. Gordon, Mr. H. Cannell, H. M. Pollett, David Thomson, Miss Hamilton, Kate Greenaway, Eurydice, Swanley Gem, Kate Farmer, Queen of the Whites, and Eureka. Twelve good double varieties are Dauntless, Vesta, F. V. Raspail, Lord Mayor, Mons. Thibaut, Emile de Girardin, General Campenau, Henry Cannell, Asa Gray, La Constitution, La Cygne, and La Quintinie. Twelve good Decorative, Show, and "Regal" varieties are Beauty of Oxtou, Duchess of Edinburgh, Mermerus, Kingston Beauty, Dr. Masters, Rubens, Queen Victoria, William Bull, Digby Grand, Duchess of Bedford, Elegantissima, and Mons. Bouchardat.

Covering Outdoor Mushroom Beds (S. L. B.).—As we have not seen the Aston Clinton mats used for the purpose named we are not able to answer your question. When Mushroom ridges are made steep, firm, well combed down, and rounded at the top very little rain can enter them, and if covered with litter, the thickness depending on the heat of the beds and the weather, we have no doubt that well-made straw mats placed over this would prevent rain injuriously affecting the beds and crops. The great majority of beds or ridges are not covered with mats at all, but with litter only, often

very thickly, and combed down with forks to conduct the rain to the ground. We have seen old Mushroom beds thus protected too dry in the centre when removed. Many persons err by making Mushroom ridges too flat for winter production.

**Shaded Passage (F. S.).**—With the exercise of a little taste a very attractive fernery might be made in the position described, and if heated to maintain a night temperature of about 45°, falling to 40° in the winter, it would enable you to grow many varieties of Ferns and be also agreeable. In the summer it could be brightened by a few flowering plants in pots, such as Begonias and Fuchsias; in the spring Hyacinths and Narcissus would render it attractive, and in the winter it would be suitable for Camellias. If your plants are now expanding their blooms are in a warm house we should not remove them, as if frost should occur they might receive a severe check. Camellias are nearly hardy, but even hardy plants are made tender by being grown in a warm house. Lapagerias would grow in such a position as you describe if you desire anything for the roof; and the fernery, if heated, would be safe for the birds, not otherwise during very cold weather.

**Raising Water from a Brook (H. W. Gunn).**—The most economical and effective method of raising water is by a ram, but whether you will have sufficient fall could only be determined by an engineer on the spot. If you write to some hydraulic engineers stating your requirements they would tell you the probable cost when particulars were taken; indeed they alone can give a correct estimate. We do not know anything of the engine or pump to which you refer, and they are probably not obtainable. We have a hot-air pump or engine which raised water for the house, and though it answers is not to be compared with the ram in economy. We do not think second-hand gas piping would be suitable for conveying the water from the reservoir to the garden. We should advise 2-inch cast iron socket pipes, the joints leaded, as the most suitable and economical. The following engineers are competent to execute what you require, and have advertised in our publications. They are mentioned alphabetically:—Messrs. Astle and Co., Park Street, Derby; Mr. J. Blake, Oxford Street Works, Accrington; Mr. Hett, Anchorholme Foundry, Brigg; Messrs. S. Owens & Co., Whitefriars Street, London, E.C.; Messrs. J. Warner & Sons, Crescent Foundry, Cripple-gate, London, E.C.

**Rabbits Eating Fruit Trees (W. A. K.).**—It is very injurious, and may be ruinous to allow rabbits or anything else to eat the bark of fruit trees. Pigments applied to the stems are seldom of permanent value. We have tried several, but they only proved effective for a time. Pure gas tar we have known to be injurious to the bark, but mixed with dried powdered clay so as to form a thick paint it is safer and equally efficacious. The best method of protecting the stems is either to fix some fine-meshed hexagon netting round them, or cradles made of strips of wood bound together at the top and bottom with wire. These are easily made, and answer perfectly. Where Furze is plentiful some persons tie this round the stems, others Briars; but cradles made of deal or any other would answer equally well if the strips are placed close enough together. In affixing them they must not press firmly on the bark, this being easily prevented by interposing soft material. If any of our readers are able to communicate the particulars of any methods that have proved satisfactory in protecting the stems of fruit trees from hares, rabbits, and other animals we will readily publish them for the benefit of others. You can scarcely err in giving a good dressing of lime to the new garden. The subsoil should be well broken up, but very little brought to the surface at once. By digging a little deeper each year and adding manure you may greatly increase the fertility of the land.

**Evergreens for Lawn (An Old Subscriber).**—You have made the position quite plain now, and we are confirmed in our opinion that large-growing Conifers or spreading shrubs would be out of place. We think the flower beds are large enough for the lawn, and the Conifers or shrubs should be in proportion to both. As we presume you desire the garden to have an attractive appearance viewed from the end A and B, we should have a pair of Thuia aurea there, C and D Retinospora plumosa, E and F Thuia elegantissima, G and H Cupressus Lawsoniana erecta viridis. With stations of good soil, such as loam, decayed vegetable matter, sand, and wood ashes, the site drained so that water does not lodge near the roots, and these not turfed over, but each plant standing in a small circular bed, would grow freely and have a pleasing appearance without encroaching unduly on the surrounding space. The pairs are alternately gold tinted and green. Cryptomeria elegans, bronzy green, would answer probably as well as the Retinosporas, and you may safely plant either of which you can get the best examples for the money, the prices of all necessarily varying with size and quality. The partial shade will not interfere with their growth. When you order the plants you will not err by sending the plan to a good nurseryman, giving liberty for other kinds of the same character to be suggested in case well-balanced examples of those named cannot be supplied.

**Making Hot-water Pipe Joints—Peas for Seed (A Twenty-years Reader).**—Had we been erecting a boiler we should have endeavoured to arrange that the flow did not come in contact with the fire. You may, however, make the joint or joints required so that they will stand the fire and last in perfect condition as long as the pipe itself. You must make the joints of iron, and this is accomplished by mixing borings, chloride of ammonia, commonly called sal ammoniac, and water together, a very small per-centage of red lead in a dry state may also be included. You must be careful not to employ too much sal ammoniac, or you will destroy the properties of the iron. For two joints a small piece about the size of a Cob Nut broken fine and mixed with the borings will be ample. As much water should be used as will moisten the whole, which will soon become heated, and in a very short time after mixing is ready for use. First of all commence caulking the joint with a piece of good rope well coated with white or red lead about three times the consistency of paint, and then complete the joint with the borings, which must be well hammered up, and they will nest up and become as solid as the metal. Peas, no doubt, will pay very well on good land if the season proves favourable and the seed is well harvested; but to grow them profitably they must be grown on the same principle as field varieties—that is, in rows 12 to 18 inches apart, according to the heights of the varieties. You must be careful to keep the

varieties perfectly true by going through and "roguing" them when in flower. If you do this and guarantee the stock true we do not think you would have any difficulty in disposing of good seed. We have no doubt that if you were to consult some of the large seedsmen about varieties of which they would be anxious to obtain stock, they would undoubtedly supply you with seed and purchase the produce. If you can make such arrangements you would thereby obtain the best market for your seed. We have known hundreds of acres grown on the system indicated in Lincolnshire.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (W. L. Bird).—1, Colmar; 2, Autumn Josephine; 3, Forelle; 4, Ne Plus Meuris; 5, Knight's Monarch; 6, Winter Nelis. The Calanthe is a good form of the variety luteo-oculata, but it does not differ materially from others we have seen except that the flowers are rather more closely placed on the raceme.

## COVENT GARDEN MARKET.—JANUARY 20TH.

No alteration. A better trade doing at last week's quotations.

### THE FLOCK.

A DAY or two before writing this article we went to see what provision of shelter for early lambs had been made by a shepherd to whose care a valuable breeding flock of some 300 ewes had been given. All we found was an enclosure

of thatched hurdles with a little penthouse in one corner, formed by laying a thatched hurdle upon two others set upright in the ground, under which lay the first lamb with the ewe. This enclosure was in a paddock on the south side of a thick belt of trees, and the position was the only good thing about it. Now this shepherd had assured us that he was master of his business, yet he had only thus made use of ample means and assistance placed at his disposal. Prompt measures were taken after an inspection to provide a proper lambing fold in this way:—A circle of ample size to take in all the flock was made with unthatched hurdles set upright in the ground, a portable swing gate and posts being set in the circle of hurdles at the best point for ingress and egress. Outside this circle and 2 feet from it came another line of hurdles, the space between the hurdles being filled closely with straw. Upon the top of this snug enclosure rested the ends of thatched hurdles, the other ends being fastened to an inner line of posts raised sufficiently high to give an outward slope to the roof so as to throw any water falling upon it outside the fold. Partitions of thatched hurdles were made snug little pens under the roof, and we had only to spread straw upon the grass for bedding to render our fold complete. Inside it there are troughs for mixed food, consisting of chaffed hay and Barley straw slightly salted, a little bran, crushed Oats, and a liberal mixture of cut Swedes, with racks for Pea and Oat straw uncut, of which the ewes are remarkably fond. The fold opens into a fine piece of pasture some thirty acres in extent, specially reserved for the lambing, and the flock will be let out upon it whenever the weather is favourable, trough and rack-feeding also being regularly practised there. Some very good and commodious racks are made there by enclosing the trunks of trees with a few hurdles, and filling the space between the hurdles and tree with whole straw. The fold and pens will be kept well supplied with plenty of fresh dry straw for bedding, and all possible care taken to keep the flock as quiet and comfortable as possible.

A moderate quantity of cattle Cabbages may be given daily if they have been so well stored as to be unfrozen, but we strongly deprecate the use either of frozen Cabbage or roots, such food tending materially to a loss of vitality, and so frequently causing abortion. Ewes should always be kept in fair condition, and for a few weeks before the lambs are due a full allowance of the diet we have enumerated is highly important, because it is then especially that the nutriment afforded by the food goes chiefly to increase the size and vigour of the *fœtus in utero*, and not to the fattening of the ewe. But it must be remembered that if nourishing food given liberally then does not fatten, it certainly strengthens the parent, and thus lessens the difficulty of parturition. A weakly underfed ewe is in much danger during parturition. There is often excessive straining followed by inflammation, owing to debility.

In a well-managed flock most of the ewes pass through the lambing quite unscathed, but there are certain cases always in which special care is necessary, but there is none that ought to prove fatal. We know full well that at one time a certain per centage of loss from straining, inflammation and abortion was regarded as quite within the ordinary course of things, but now we know how needless such losses are. For all cases of straining the right and safe course of action is for the shepherd, if necessary, to extract the lamb from the ewe—a little practice soon enables him to do this quickly—then to carefully and gently sponge the vagina with warm water, and then to apply a mixture of seven parts of olive oil, and one part of Calvert's carbolic acid with a female syringe. We use an ordinary pewter syringe, one, or at most two, applications being all that is required, for it acts like a charm, and the ewe is free from all violent pain, straining ceases, and food is soon taken again. Violent straining sometimes causes protrusion of the uterus, especially in old ewes. We never allow sheep so affected to breed again, and if the protrusion is excessive a piece of stout

twine is passed round it as high up as possible and tied tightly. The ewe apparently suffers neither pain nor inconvenience, and in a short time it decays and falls off; the ewe is then fattened and passed on to the butcher. Swollen udder seldom occurs, but it may do if a ewe loses its lamb and it cannot be induced to take another. The remedy is as simple as it is efficient. Equal quantities of Eau de Cologne and olive oil poured into the palm of the hand and rubbed gently and persistently over the swollen udder soon softens it, so that the milk can be drawn from it, and there is very little if any subsequent difficulty.

With care, gentleness, and watchfulness, success should attend our charge. Results now, however, are undoubtedly influenced by our treatment of the ewes throughout the year. An undue strain was put upon many a flock last summer owing to a want of grass upon the meadows, or owing also to the lambs being kept late with the ewes. We cannot venture upon such rash measures with impunity, and it is probable that there will be weakly lambs and losses among ewes now in such flocks.

#### WORK ON THE HOME FARM.

Advantage has been taken of the frosty weather to cart manure on to the land not yet to be ploughed, but to be put into large heaps and covered with soil to be ready for the root crops. We cling to the use of farmyard manure for roots because of the moisture as well as nutriment which it affords the young and growing plants, enabling them as it does to pass unscathed through periods of drought to which they would otherwise succumb. But we only use enough of it to fill the space immediately below the roots, the soil generally being enriched with artificial manure. The cows and young stock always to be found upon the home farm afford a supply. On other farms it is with pigs and not bullocks that we manufacture our manure for roots, for bullocks have so seriously fallen off in value that it is only very choice well-bred beasts that grow fast and come to early maturity that answer now. Some writers hopefully predict better times, but we as yet fail to see upon what their calculations are based.

We continue passing pigs in large numbers quickly through our yards. Most of them enter as store pigs and pass out again in a few weeks as porkers, plump, compact, and fit for the butcher. Breed tells very much in this work, compact chubby animals being much more profitable than those of larger frames. These latter are held in reserve for bacon hogs, and they are forced on quickly, for we have no faith in keeping them, or, in fact, any animals kept for profit a day longer than is necessary. Pig-keeping and dairy farming generally answer well, and a certain number of pigs should always be kept with the dairy herd on the home farm. We have increased our number of pigs this winter to meet an emergency. So much Barley was exposed to heavy rain after it was ripe that the grain became discoloured and prices ruled low—so low that it became evident it would answer our purpose to convert as much of the inferior grain into pork as we could, and so dispose of it. No special breed need be recommended for this purpose. There are plenty of good local-bred pigs everywhere to be had if we search for them, so that there need be no special outlay to procure good ones. It is for this, among other reasons, that pig-keeping may be taken up or left off with such profitable celerity. The matter may be one of weeks or months only. Nor need we go to the expense of building model stys for them; shelter from rain, plenty of clean straw, and good wholesome food being all they require.

#### REMARKS.

- 10th.—Fair early, slight fog in afternoon, and a little snow from 5 P.M.; total depth at 9 P.M. half an inch.  
 11th.—Damp and rainy all day, thawing, cold clear night.  
 12th.—Bright, fine, and frosty morning; cloudy afternoon, with a little snow; rain in evening; wet night.  
 13th.—Wet early; westerly squall at 10.45 A.M., with heavy sleet and rain; fair afternoon.  
 14th.—Windy and cloudy till 11 A.M., fine and bright after.  
 15th.—Dull morning, wet afternoon and evening, fine clear night.  
 16th.—Fine and fresh; squally in evening, with rain at 10 P.M., and heavy rain at 10.30 P.M.  
 Very changeable week, with rain, snow, and sleet, and sharp changes of barometer.  
 —G. SYMONS.

### GREENHOUSE RHODODENDRONS.

**C**ULTIVATORS are indebted to the Heath family for some of their most useful and handsome plants, and the Rhododendrons, Azaleas, and Ericas alone would take a foremost place in floral importance. Rhododendrons particularly present a variation and beauty that cannot be surpassed in any one genus, and in some respects they are unequalled. The shrubbery department of gardens may be said to have been revolutionised by the introduction of hardy Rhododendrons, and beds of these plants now occupy an important position in most establishments wherever the soil is in any degree suitable for them. The North American *R. catawbiense* was a grand acquisition, and when the hybridisers had brought their skill to bear upon this, *R. caucasicum* and *R. arboreum*, a race of noble shrubs was obtained that speedily found innumerable admirers. Who can visit such gardens as Baron Schröder's at Egham (where a grand collection of these is now grown), at the time the plants are in flower, without being both surprised and delighted at the rich colours furnished by the bold trusses of flowers with which the shrubs are loaded? In the early summer months thousands of gardens are rendered gay with these Rhododendrons, from the warm southern counties to Lancashire and Yorkshire, and whether in formal beds, bold clumps, or clothing the sides of elevated ridges as at Chatsworth, they are alike beautiful, though the last-named appears more natural and picturesque.

Another magnificent group comprises the natives of the lofty Himalayas, the stately *R. argenteum*, *R. Aucklandi*, *R. Nuttalli*, and many others which Sir Joseph Hooker discovered in the Sikkim district, and that have since become the favoured occupants of many conservatories and winter gardens; or in sunny Devon and Cornish gardens, reproducing out of doors the attractions of the Indian Alps. Some gentlemen have made specialties of these, as the Hon. and Rev. J. T. Boscawen and the late esteemed J. H. Mangles, Esq., and their collections have become widely famed in the horticultural world.

A third group must be added containing the "greenhouse" Rhododendrons, totally distinct from both the foregoing, and, if of more lowly growth and less imposing appearance, they are certainly equally charming and useful. We owe the two preceding types chiefly to North American and Himalayan species; but now, turning to the tropical Malayan Archipelago, we find amongst the luxuriant vegetation of those islands several Rhododendrons widely differing in characters. In Borneo especially they are very numerous, growing upon the branches and stems of trees like the epiphytal Orchids in the dense forests which clothe some of the mountains to great elevations. In Java, Malacca, and other districts are also found several species that have been employed to excellent advantage by the hybridiser, and have assisted in producing the charming race of plants now so well known. Amongst those which have played a prominent

part in the work of improvement is *R. javanicum*, which seems to have been the first introduced to this country, being one of those which the traveller, Mr. Thomas Lobb, collected in 1847 for Messrs. Veitch & Sons, then of Exeter. It was first found or noted by Blume, by whom it was named *Vereya javanica*, a title since sunk in *Rhododendron* as not being separated by characters of sufficient importance to deserve generic rank. To the natives it was known as *Gaga Mirha*, and it was moderately abundant in forests at an elevation of 4000 feet. In growth the plant is naturally somewhat straggling, and not of the bushy habit distinguishing the American species. Its flowers are borne in dense heads, are shallow or Azalea-like in form,  $2\frac{1}{2}$  inches in diameter, of a dark orange-scarlet colour, and purplish in the centre. It has been especially valuable for the richness of its colour, which has been imparted to numbers of handsome descendants.

About the same time—namely, in 1848—was introduced another species, *R. Brookeanum*, from Borneo, the flowers of which are rather more tubular than *R. javanicum*, and of a bright yellow colour. Mr. Hugh Low gives an interesting account of this plant in his work on "Sarawak," thus describing the finding of what was justly considered a floral treasure:—"I shall never forget the first discovery of this gorgeous plant. It was epiphytal upon a tree which was growing in the water of a creek. The head of flowers was very large, arranged loosely, of the richest golden yellow, resplendent when in the sun. The habit is graceful, the leaves large, the roots are large and fleshy, not fibrous, as those of the terrestrial Rhododendrons. It is the least common of all the genus in the island, and has many varieties, which differ in having larger flowers and leaves, the former of a more or less red colour. Very high and large trees in damp forests are its favourite haunts." From this, crossed with other forms, have been obtained most of the yellow-flowered hybrids, and the combination with richer colours has produced many beautiful intermediate tints.

Still another year later—1849—the lovely *R. jasminiflorum* made its appearance, and at once became a favourite with plant lovers. Writing some time ago Mr. John Smith, the ex-curator of the Royal Gardens, Kew, remarked concerning its *début* as follows:—"At the truly splendid exhibition of flowers at Chiswick in 1850 few plants excited greater attention among the visitors than this from the nursery of Messrs. Veitch at Exeter. Many excelled it in splendour, but the delicacy of form and colour of the flowers, and probably their resemblance to the favourite Jasmine, attracted general notice." That this encomium was amply deserved can be easily imagined, for even now there are few stove plants to equal it in graceful beauty. The long tubular flowers are sufficiently like the white Jasmine to render the title a suitable one, but they are larger, and though generally white, there is sometimes a tinge of rose that serves to heighten their charms. Like the others, the plant is rather deficient in compactness of habit, but it has been considerably improved in this respect by continued crossing with that object in view. It is a native of Malacca, where it was found by Mr. T. Lobb at an elevation of 5000 feet above sea level.

Of comparatively recent introduction is *R. Lobbi*, which was exhibited and certificated at South Kensington in October, 1869. It is a native of Borneo, and has been thought by some to be identical with *R. longiflorum*, a species described by Lindley in the London Horticultural Society's Journal. It has bright crimson flowers, with a tube somewhat like *R. jasminiflorum*, but not quite so long, and they are borne in dense heads at the ends of the stems or branches. The leaves are oblong, bright green, and arranged in whorls round the stems. I do not know the precise habitat of this species, but *R. longiflorum* is found "near Sarawak on high trees in low damp jungles." To these might be added *R. Edgworthi* and *R. ciliatum*, which have also been employed in the hybridising, but as

they are of minor importance as regards the effects produced the mention of their names will suffice.

Such distinct plants had not been long in the hands of the introducers before some attempts were made to effect crosses between them, and we believe that the first results fell to the share of Mr. Taylor, who succeeded in obtaining several intermediate forms, one of the earliest of which bears his name. Several others followed, and the greenhouse hybrid Rhododendrons quickly took a place amongst established favourites. Diversity of colours has been obtained, lovely flowers of wax-like substance in dense umbels of ten to fourteen; the plants have been gradually rendered more bushy in habit, and all that close attention to their improvement could ensure has been effected. The latest additions are chiefly due to Messrs. J. Veitch & Sons' foreman, Mr. Heale, and for several years past a number of novelties has been brought before the public each season. In the past six years about thirty hybrids have been certificated, and we may expect many more yet, for large numbers of seedlings have been raised, the best of which are being continually selected.

Tracing the results of the intercrossing of the species named, and again with the hybrids so raised, we find that they have proved a prolific source of handsome additions to these beautiful plants. *R. javanicum* and *R. jasminiflorum* were crossed, and produced a number of seedlings, from amongst which an especially fine form was selected and named Princess Royal, a hybrid that has been of inestimable value in after-crossings. By fertilising it with pollen from *R. Lobbi*, and also by making the latter the seed-bearing parent, some of the best hybrids of the group have been obtained, such, for instance, as Princess of Wales, Duchess of Teck, Duchess of Edinburgh, Prince Leopold, and Duchess of Connaught, all charming hybrids. Princess Royal has also been crossed with *R. Brookeanum*, and from this union was obtained Princess Alexandra. *R. Lobbi* has been similarly crossed with *R. jasminiflorum* and produced Princess Helena, which in its turn was crossed with *R. Brookeanum gracile*, and yielded Crown Princess of Prussia and Princess Thyra.

These may be described as the preliminary stages in the improvement of greenhouse Rhododendrons, for since the appearance of the most recent of those previously named—*i.e.*, Duchess of Connaught, which was certificated in 1881—numerous additions have been made to their numbers. Referring only to those that have been similarly honoured to that first mentioned, we have no less than twenty-eight, comprising the following, all of which have been exhibited by Messrs. J. Veitch & Sons. In 1882 eleven were certificated, and amongst them were the trio of double forms, *balsamiflorum*, *balsamiflorum album*, and *balsamiflorum aureum*, which are salmon red, white, and golden respectively. These were the first distinctly double Rhododendrons of this group, and the flowers are so beautifully formed that would prove invaluable for buttonholes or bouquets. The other single varieties of the same year were Aurora, orange; Excelsior, large buff, with red stamens (from Princess Royal  $\times$  *javanicum*); Favourite, a soft pink; Monarch, bright orange (from Princess Alexandra  $\times$  Duchess of Edinburgh); Sir Beauchamp Seymour, pale buff, stamens rose-coloured; Sir Garnet Wolseley, reddish salmon, very large; Star of India, buff; and Queen Victoria, bright yellow, very pretty and of good habit.

The years 1883 and 1884 brought out six and four hybrids each, as follows:—In the first-named year Baroness Schröder, dark yellow and red stamens; Brilliant, rich scarlet, very large; Diadem, orange scarlet; Princess Christian, pale pink, charming; Scarlet Crown, orange scarlet; and Triumphans, brilliant scarlet. In 1884 Conqueror, large flowers, dark scarlet; Empress, salmon rose; President, yellowish buff, pink margin; and Princess Beatrice, pale creamy buff tinged with rose. Last year no less than nine seedlings were certificated, and all well deserved the honour. They were—

Apollo, scarlet, the flowers in very large heads of ten to fourteen; Cardinale, rich scarlet; Curtisi, crimson; incarnatum floribundum, buff and rose; Indian Yellow, clear yellow; Militaire, scarlet; Minerva, soft yellow with red stamens; Pearl, white and rose tinted (from Princess Royal and Aucklandi); and Teysmanni, bright yellow, the flowers very neat in form. It will be seen from those noted that a considerable range of colours is now secured, but no doubt other tints will be added from time to time, and if a few other species could be found of different colours some valuable additions might soon be expected.

These notes have extended to such a length that a few remarks on culture must be reserved for another contribution.—L. C.

### AMONG THE VEGETABLE NOVELTIES.

IN continuation of my notes which appeared some months ago, I have a few words to say about the Brassicas, which I was not then in a position to express. I have been very glad to see notes about vegetables appearing every now and then in our Journal, for they are highly appreciated by me, who am only a vegetable and fruit grower. Flowers truly I love, but I have come to the conclusion that in their cultivation I shall never be very celebrated.

Chou de Burghley is no longer quite a novelty, but the strain is improved. Mr. Gilbert kindly sent me some plants from which I am now cutting heads singularly free from the rather strong flavour of the earlier stock. I find them very delicate and Marrow-like.

Chou de Gilbert is another little stranger from Burghley, and if Mr. Gilbert goes on like this he will be the father of a numerous family of Chous. This is an improved Brussels Sprout, being free from the strong flavour of the latter. The strain being hardly settled yet, I have not had a very good opportunity to judge, but if from the few I have I can form a just estimate, I should say that this novelty will be a great acquisition. Burghley Pet Cabbage takes after its worthy parent the Chou in flavour, but is more dwarf, hearts in quicker, and is a Cabbage without the Broccoli shoots inside.

Brussels Sprouts I tried in three varieties—Daniel's Colossal, Webb's Matchless, and Aigburth, and I must give the palm to the last for everything. To those, however, that prefer the small buttons I cannot recommend it, for the sprouts are large and solid.

Celery—I tried Northumberland White (which I obtained from Stuart & Mein), Manchester Red, and White Plume. The first, which is a large kind, is excellent in every way. I have had very fine sticks as brittle as glass, and I find it of very good flavour and hardy. Manchester Red is good, but nothing out of the common. White Plume will do for soup in autumn and until snow and sharp frost come, and then where is it? I have several rows, but there is very little trace of them left, although they were partly earthed up.

Lyon Leeks are fine and of good quality. It is a vegetable I like, and is extremely beneficial to many persons.

To those now giving in their orders for seeds I would say, Do not omit Duke of Albany Pea and Victor Potato. Both are sterling novelties with which every grower will be pleased both for quality and quantity.—H. S. EASTY.

### WINNING ROSES.

IN his interesting article in the "Rosarian's Year Book" on "Winning Roses," Mr. T. B. Hall carries on the pleasant series of Rose selections based upon actual practice at the exhibitions of the last two seasons; and though the varieties enumerated do not stand quite in order of merit, owing to their being arranged only according to the number of blooms shown, independently of the number of plants from which these were obtained, still the averages can easily be struck for comparison with the former lists of Mr. Whitwell and Mr. Mawley. Of course, as Mr. Whitwell pointed out in his article in 1884, to take absolute averages would be most misleading; for instance, one result of such a proceeding in the present case would be to place Mabel Morrison in the first twelve, a position it certainly cannot claim to occupy, in the south at any rate, although in wet weather it occasionally travels safely to a show. But by taking into consideration the proportion of the number of blooms shown to the number of plants grown, in the case first of those Roses exhibited not less than thirty times, then of those shown not less than twenty, fourteen, ten, and seven times respectively, it will be seen that Duchesse de Vallombrosa heads the poll by a large majority, with

Captain Christy as a good second, and an unexpected fourth in Louis Van Houtte. The excellent figures of the light Roses all through, probably owing to the two hot seasons, are very noticeable; thus Madame Lacharme, Madame Hippolyte Jamain, Princess Mary of Cambridge, Merveille de Lyon, Violette Bouyer, and Mons. Noman have all good records, the last-named variety especially making a wonderful success for a Rose generally considered shy as a cut-back.

Naturally the bulk of the first forty-eight is identical with the selections of recent years; but there are included several less generally grown varieties, mostly dark Roses, which are worthy of notice. Of these Dingée Conard appears fourteenth in the list; and though sent out ten years ago by E. Verdier, does not seem to have been widely cultivated. It is, however, a beautiful and well-finished Rose, between Charles Lefebvre and Madame Victor Verdier, of moderate size, while its rich colour stands well. No. 23 is another 1875 variety (Cant's Prince Arthur), a most useful all-round Rose, deservedly well placed, but one which is surprisingly seldom recommended. It is commonly described as a dark Général Jacqueminot, which it resembles in most respects except in colour, but it is a better flower; and as a free dark Rose which is deep-petaled and does not burn it is very dependable. Duke of Connaught again (Paul 1876), which comes out twenty-eighth, has been exceedingly reliable in the late hot summers; and though its raiser has emphasised the fact of its not being of great size, still it is large enough as a rule for practical purposes, and is a good traveller.

No. 38 is Madame Ducher's promising seedling of 1880 (Rosieriste Jacobs), a free-blooming dark Rose of fair size and good shape, with good lasting qualities; in colour, coming between Horace Vernet and Duc de Wellington, the latter of which it closely resembles in habit of growth. The last of the dark Roses not included in former forty-eights is Lord Macaulay (W. Paul, 1863), forty-first in order, which is also probably often left out of fancy selections from being considered rather small; but though beautiful in colour it is a somewhat stunted grower.

In addition to Mabel Morrison (No. 44) above mentioned, which is still one of the prettiest white garden Roses, No. 45 is Madame Sophie Fropot (Lévet, 1876), a very vigorous and useful big-petaled pink Rose, which at one time was decried as too thin, but it has proved a very useful exhibition flower, and it does not fade lilac as so many pink Roses do. Lælia (or Louise Peyronny), a useful light rose-colour if it were a more vigorous grower, is placed forty-seventh.

Of the first forty-eight, Marie Rady averages the worst, but is notoriously capricious; as are Emilie Hausburg, Annie Wood, Comtesse de Serenye, and Star of Waltham. But the poor display afforded by several well-known names tends to strengthen the impression made by Mr. Whitwell's 1884 list, that a good many varieties are living on their reputation, so to speak. Thus it appears necessary to grow Madame Victor Verdier at the rate of four plants for each flower, and to insure a bloom of Sénateur Vaisse good enough to show in a winning stand even more trees seem requisite. Maréchal Vaillant is not quite so expensive, but John Hopper, Duchesse de Caylus, and Duc de Rohan are hardly any better; while it takes six plants of Pierre Notting to furnish a solitary flower. That Thomas Mills should beat the record, and only supply three blooms from thirty-two plants, seems surprising in a Rose so commonly recommended for the north, and which ranks twenty-second in Mr. Whitwell's 1884 list; but presumably in spite of its splendid petal it is not full enough to stand a journey anywhere in such a baking summer as that of 1885. The heat is also enough to account for the relatively low positions of the dark Roses that are liable to burn, such as Prince Camille de Rohan, Abel Carrière, &c.; while E. Y. Teas is not a strong grower, and probably would not succeed so far north so well as in the southern counties; but on the other hand the excellent average of Xavier Olibo should be noted.

The recent Ulrich Brunner, Alfred Dumesnil, and Comtesse de Paris all give a good average, and are all first-rate Roses; while excellent evidence of Mr. Hall's well-known skill as a cultivator is afforded by the number of blooms which he succeeded in staging of Lord Bacon, Lady Mary Fitzwilliam, and Violette Bouyer from newly planted trees.

On page 52 of the "Year Book" Mr. A. Hill Gray mentions the pretty Tea-scented Comtesse de Caserta, sent out by Nabonnand in 1877, which is one of the freest-flowering of Roses even in these unfortunate islands. A useful mode of treating it to obtain late flowers in autumn is to put a few buds as soon as they can be got in June upon dwarf Briar stocks, upon which they start into growth immediately, and furnish abundance of bloom by September. The fact of the flowers not being very full is in favour of their opening well during damp autumnal weather; and the petals being large they make capital long buds for cutting.

Of the other Tea Roses here described by Mr. Gray as not gene-

rally grown in England perhaps Olympe de Trecinay (Damaizin, 1859) is only Madame Berard under another name, since in course of long periods things invariably get re-named, and there is good authority for stating that Madame Berard was first sent out A.D. 1370; Marietta de Besobrasoff having been distributed (presumably by an ancestor of the present prolific raiser of the same name—Nabonnand) nearly 200 years earlier.—(*Gardener's Magazine*, vol. xxviii., pages 368, 384.) Monplaisir (Guillot, 1868) is not likely ever to be popular over here, as it so constantly comes quartered, and is almost always coarse and wanting in finish in this climate.

It would be interesting to learn whether the lines which Mr. Gray gives about the sepals of the Rose were quoted to him in Spanish or in Latin. The celebrated botanist, Robert Brown (whom Humboldt styled "*Botanicorum facile princeps*"), cited, as showing how observant the old monks were, the following Latin lines which he had come across in some old book in the British Museum, and which describe the peculiarity of the Rose calyx much as Mr. Gray gives it:—

"*Quinque sumus fratres, sub eodem tempore nati;  
Duo barbati, duo sine barbâ creati;  
Quintus barbatus, sed dimidiatus.*"

Which may be thus freely translated—

"Five brothers we, together born,  
Two bearded, two beards ne'er have worn;  
The fifth a beard wears on one cheek,  
The other being shav'n and sleek."

—T. W. G.

### STRAWBERRY PLANTS IN WINTER.

IN respect to the methods of preparing Strawberry plants for forcing and preserving them during the winter there does not appear to be (if we refer to the remarks made by "*A Kitchen Gardener*" and "*A Northerner*," pages 534 and 584, last vol.), that unanimity of opinion which might reasonably be expected after years of experiment and practice in these simple operations. It would seem as though we had not yet discovered any really sound or safe principles on which to rely with confidence; for while one correspondent advocates a somewhat dry treatment during the resting period, the other recommends that the plants should never be allowed to become dry, and for this reason he advocates the practice of plunging the plants out of doors in an upright position either in ashes or leaves. That the Strawberry plant is perfectly hardy in the usual acceptation of the term everyone will readily admit, but its worst enemy in winter is not cold but damp; and if we keep this fact in mind I think we shall decide that the method recommended by "*A Kitchen Gardener*," of simply laying the plants on their sides, is on the whole less objectionable than that of plunging them in an upright position, because the plants are by such means kept in a condition more nearly like that to which they are naturally accustomed. No doubt, when in spring, as the sun's power increases, and especially when drying winds prevail, the drying process would soon become extreme and prove injurious unless the plants were occasionally watered, but through the winter months the plants so situated never become excessively dry, because they absorb sufficient moisture through the pots to keep them in a healthy condition.

This practice is, however, open to two objections which, although not serious, are sometimes inconvenient and difficult to counteract. The first is that when the pots are thus laid down three-fourths of their surface, where the best roots are situated, are fully exposed to the weather, and although the Strawberry plant is perfectly hardy under natural conditions, yet when the soil in the pots is wet and severe frosts occur, the whole are liable to be frozen into complete balls of ice, and when a thaw takes place not only are many of the pots destroyed, but the plants must also suffer seriously from such unnatural treatment. Of course they may be protected by a covering of dry straw, fern, or other litter, but here arises the inconvenience attending the method, and not only this, but sudden frosts cannot always be foreseen, and the necessary protection may not be given; and, again, in long-continued frosts this very protection may, and sometimes does, prove a source of mischief by partially blanching and weakening the plants. The second objection is not so important, being simply a question of space, which in the winter season when comparatively few plants are exposed out of doors is not difficult to provide, and yet where from 3000 to 5000 plants are prepared it is not always convenient either to find a suitable position or to give that extra attention which they require when so arranged.

On the other hand the practice advocated by "*A Northerner*" of plunging the plants in an upright position either in ashes or leaves, while it effectually overcomes the evil of undue exposure of the roots already referred to, still it is open to a more serious objection. In very dry positions or in dry winters no harm may ensue, but in damp situations or in wet winters this practice often leads to most disastrous results, by the plants being kept in a constantly wet and soddened

state during the period of rest, when comparative dryness should be their condition. Some years ago, in order to test this practice, I subjected a portion of my stock to this treatment for three successive years. The first and third winters were excessively wet, and although the plants in the autumn were good in every respect equal to those stacked in the usual way on their sides in ashes, yet in the spring they presented a very different appearance, the majority of them being yellow and sickly, while many of them were quite decayed. The second winter was dry and severe, and the plants so treated were in spring quite equal in health and vigour to those stored in the ordinary way, proving most conclusively that continued wet was the cause of the evil. When plunged upright, and when frost and rain quickly alternated, I have frequently seen the surface of the plants covered with ice level with the rims of the pots, the crowns being encased therein—not a very comfortable or safe condition I imagine for even the hardiest plant to be placed in.

These experiments convinced me there was no advantage to be gained by plunging them in an upright position, but rather the reverse. I therefore continue to stack them in ashes, and have never failed from so doing. This old-fashioned method commends itself in several ways. It is quickly done, they occupy but little space, the foliage and crown of the plant is freely exposed while the roots are fully protected, and when so placed they need no additional protection even in the severest weather, plainly proving that the Strawberry plant is perfectly hardy when comparatively dry. When stacked in this manner the soil and roots during winter appear to absorb just sufficient moisture from the damp ashes to sustain the plants in perfect health, and in spring when they become dry they should be taken from the stack, the ashes levelled, and the plants placed thereon and watered when necessary. I can fully endorse the statement of both correspondents respecting the inadvisability of very early forcing, nor is there the least advantage gained by placing them either in frames or cold houses. When taken indoors they should be gently excited into growth, gradually increasing the temperature till the fruit is coloured, when a somewhat cooler temperature and dryer atmosphere is desirable.—T. CHALLIS.

#### ANALYSIS OF SOIL.

MR. TAYLOR rather disappointed me in his answer to my questions. I gather from it he cannot analyse the soil himself, consequently he would, in case Vines did not thrive, only guess at the treatment required, although he would not do much harm with diluted cow urine, as it contains a large amount of nitrogenous food in addition to potash. I have an elementary knowledge of chemistry, but it seems to me to lose half its value through ignorance of analytical chemistry. Some time since the late "Single-handed" gave an instance of how he was deceived by some turfy loam used for potting, a little knowledge of analysis would have prevented the mistake. Mr. Taylor himself when at Longleat applied lime to his Vine borders, and if my memory is correct (for I have not got the article) it was little more than a lucky guess that led him to do so.

Mr. Bardney recommends lime to be used for Vine borders if the soil does not contain it in quantity, and illustrates the subject by referring to a Cabbage bed. I commend to his notice the following passages, copied from "Warrington's Chemistry of the Farm." "Burnt lime is much more powerful in its action on vegetable matter than chalk or marl; it should be used with discrimination lest the humus of the soil be unduly diminished." And again, "The general effect of lime is to render available the plant food already in the soil, without itself supplying any significant amount; liming cannot therefore be successfully repeated, except at considerable intervals." In the last few lines Mr. Bardney tells us if the Grapes are not colouring well to give lime. Now, Vines need not be allowed to suffer before the lime is applied. To determine whether lime is present put a little of the soil in a glass and pour some vinegar on; if it effervesces lime is present, and the amount of effervescence will give an idea of the quantity of lime. If a gardener possessed sufficient skill to make a partial analysis and so determine the composition of a given soil it would reduce blunders to a minimum. I have grown Roses, Dahlias, and Chrysanthemums up to exhibition form without any scientific knowledge—that is, before I commenced to study chemistry, but undoubtedly it is well to have an elementary knowledge of the same, and I should think better still to know something of analysis. I ask other correspondents to give their opinions on this subject with suggestions to intending students and any information they may themselves possess.

I do not agree with "Thinker" concerning the Gros Colman question. Such a gardener as Mr. Taylor describes would not so neglect pot Vines. And, again, if want of water had made the leafstalks droop, the leaves too would have followed suit, and Mr. Taylor distinctly says the leaves remained rigid.—A. L. G.

CARTER'S ASHTON FLUKE EARLY KIDNEY POTATO.—Last year, in reply to a private inquiry from a gardening friend in Cheshire as to the best second early kidney for a gentleman's table, I recommended this variety. To-day I had a note saying the variety was not so much of a success as I anticipated it would be, adding, "The soil was somewhat cold and retentive, and of marly clay formation." This information was

not previously given. Had it been I should probably have recommended Porter's Excelsior or Schoolmaster. This variety, being one of the hand-somest kidneys and of the finest quality grown, will not suit "a cold retentive clay" in my opinion. Perhaps you would permit me to ask the opinion of others who have grown this variety through your columns.—W. J. MURPHY, *Clonmel*.

#### CYPRIPEDIUM CENANTHUM SUPERBUM.

THREE useful old *Cypripediums* have been concerned, directly or indirectly, in the production of this handsome hybrid, and it might therefore be expected to exhibit, as it does, a combination of excellent characters. One of the earliest hybrids raised in this genus was *C. Harrisianum*, which Mr. Dominy obtained from *C. barbatum* and *C. villosum*, the only other hybrid *Cypripedium* secured by the same raiser being *C. vexillarium* from *C. barbatum* and *C. Fairrieanum*. Employing *C. Harrisianum* as one parent, Mr. Seden crossed it with *C. insigne*

Fig. 11.—*Cypripedium ceanthum superbum*.

Maulei, and from the seed thus obtained *C. ceanthum* was raised. There is always much difference in the seedlings from any cross, and so in this case, one proved much superior to the others, and received the title *C. ceanthum superbum*, as in another example we have *C. Leeannum*, and *C. Leeannum* from similar crosses between *C. insigne* and *C. Spicerianum*. *C. ceanthum superbum*, of which a flower is shown in fig. 11, partakes somewhat of the characters of *C. insigne* Maulei, having a margin of white to the dorsal sepal, which is of a purplish red colour in the centre, and lines of nearly black spots. The petals are of similar colour, also with dark spots, and the lower sepals are greenish. It was sent out last year by Messrs. Veitch & Sons, Chelsea.

#### THE CULTURE OF PEAS.

IN my remarks recently I offered to furnish a few more notes, which I will now do, but it should be observed that in describing the sowing of Peas I intended to say that they are better sown closely together in the rows, particularly the early varieties which were then referred to. Just before the growths show themselves through the soil, stretch a piece of strong cotton or thread from end to end of each row to keep the birds from destroying the young plants. I recommend cotton or thread because it is much cheaper than covering the rows with a net, and it is quite as useful for frightening the birds. I have another reason for

preferring the thread, and it is this: when the plants have grown to the height of 5 or 6 inches towards spring we often have a fall of snow, and I have found that the nets hold the snow for a certain time until the weight presses them to the ground, and I find after that the Peas never do so well as those that have thread strung from end to end. Watch the plants, and if you notice the slugs have been destroying any of the plants give a good dressing of unslacked lime just at dusk. Lime is preferred to soot, because it is better for the Peas, a quicker destroyer of slugs, and rather cleaner to use.

When the Peas are ready for earthing up and the plants are very numerous I draw a number out of the rows, and find the others grow much more sturdily; but I always leave more plants in the rows this first time of drawing than is wanted to stand for a crop, because the slugs, I find, very often eat the plants just above the earth, also strong wind perhaps breaks some of the plants, therefore I find it is better to leave a little over a crop than under.

I recommend those who have the trenches ready to make a sowing as soon as possible of Carter's Telephone, Stratagem, and Pride of the Market, Laxton's Evolution, or Everlasting, as I call it, for it bears fine pods of peas a longer time than any Pea I have ever grown, also Laxton's Charmer, Webb's Wordsley Wonder, House's Perfect Marrow, and Culverwell's Telegraph. There are many other good Peas, but I know none better for profit or exhibition than the above named.—HY. MARRIOTT.

### THOUGHTS ON CURRENT TOPICS.

WHEN reading the elaborate commentaries of "Utilitarian" and "J. T. S." last week on a few dreary paraphrases (page 3) on the relative positions of private and professional market gardeners and cognate matters, one thing was impressed rather forcibly on my mind—namely, that my readers and critics will never all agree, either to present me with a testimonial, such as a polished pen, or invest me with the distinction of being the "ugly duck" of the Journal family. I therefore derive consolation from a diversity of taste.

IN accepting the invitation of the first-named correspondent to "crack a few nuts" he has provided, I must remark at the outset that my interlocutor is placed at a natural disadvantage, inasmuch as he is confessedly an interested party, even to such an extent that he sits in judgment on his own case. What wonder, then, he should give the verdict in his own favour? But what weight can a verdict have under those circumstances? That is, I think, a fair point, not to be overlooked in the consideration of the matter at issue. "Utilitarian" sells, by order, the produce from his master's garden; it pays him to do so, benefits others, therefore is right. Possibly it may be. We shall see.

ONE fact appears to be established that I was a little anxious to elicit. Some rather hard things have been said of the owners of gardens making a profit out of their luxuries to the prejudice of struggling toilers in their vicinity. I am not one who believes in the grasping proclivities of the nobility and gentry of this country. On the contrary, I am of opinion there is no more just and generous class of individuals, if I may so call them, on the face of the earth; and I fear that in not a few instances advantage is being taken of their good-heartedness in the systematic clamour for the repeated abatements of rents; but in this matter of selling garden produce in competition with market gardeners it has come out at last that gardeners, not masters, are at the root of at least some of it, because of the "commission." Thank you, "Utilitarian," for that significant and unasked-for admission. You are a good and faithful servant, I doubt not, looking well and honestly after your master's interests, and your own.

NOW to business. Your correspondent has never heard a "single" market gardener complain of his competition, nor a married one either, perhaps; but let that pass. If the seat of his operations overlooks the highly cultivated market garden farms in the Thames Valley, the owners of them are not much more likely to complain than the directors of the Great Western Railway would if a new one-horse carrier commenced business by the side of their line. It is the smaller cultivators who are striving, almost in vain, all over the country, to make a livelihood from their land and vineries, who feel themselves handicapped because of the enormously greater per-centage they believe themselves rated on their property in comparison with their great rivals, who profit by private market gardening. I am neutral in this matter, and have raised the question with the object of seeing what there is in it. There may not be the great inequality of rating that many suppose, and in that event there is no real grievance. What I think is this. If a gentleman systematically buys plants to grow with the object of selling them again at a profit, he should be rated exactly on the same scale as if he were a nurseryman; and if another grows fruit, flowers, and vegetables with the same object in view—profit, he should be assessed at the same rate, in accordance with the value of his land and structures, as regular market gardeners are in his district, and no more. Has "Utilitarian" anything to say against that? If it is unfair I ask him to point out wherein it is so.

EQUITABILITY in the matter of rating would not, in my view, limit

the production of garden produce in the slightest degree. As much as ever would be produced, and it would reach consumers just as cheaply as it reaches them now. The difference would be this—Those cultivators who are rated too high now would have their profits slightly increased, because of the rating reduction; while those rated too low would have somewhat lessened profits in accordance with the increase of the rates. They would be placed on an equality as traders, and I cannot conceive any fair-minded person complaining of that. The difference would probably be slight in either case in the majority of instances; but slight or not, I cannot think it right for one trader to enjoy privileges at the expense of another. If "Utilitarian" thinks differently let him state "the reason why."

IN my opinion the practice of sending large quantities of produce from private gardens to London does not benefit consumers to anything like the extent that is popularly supposed. I have helped to clear more than one house of Grapes, and gather and pack other produce for Covent Garden. This was as often as not done as a matter of home convenience. The result was often disappointingly small "returns;" but those who think the produce was sold to the public at correspondingly low prices are greatly mistaken. The middleman, greengrocer, call him what you will, is the gainer in these transactions, not the public. Private garden stuff is a gold mine to these enterprising individuals. They buy pretty much at their own price and sell too, and in the former case it is as low as possible and the latter as high. This is what is called "doing business." I am intimately acquainted with a gentleman who gave 5s. 6d. a pound for Grapes at a London fruiterer's that were grown in the gentleman's own garden and sold therefrom for 2s. 6d. a pound, and on his return home the gardener had not a very pleasant quarter of an hour. If means could be devised of getting the produce from gentlemen's gardeners more directly to consumers its sale would be a blessing to millions, whereas it is now mainly a great blessing to middlemen and a small one to gardeners in the shape of the "commission," which as a rule they well earn by good management and hard work. As the London butchers get the profits from farmers' flocks and herds, so do middlemen chiefly benefit by the culture of garden produce. Things have come to the pass that is hurling in the case of the hungry lawyer and his litigants—"A shell for thee; a shell for thee; the oyster is the lawyer's fee." Who can point out a remedy? If an "Utilitarian" can, the greatest blessing of all will be his having entered into the arena of garden literature. I have read a few of his previous articles with interest, but his last bore the stamp of great ability, and if he is a novice, which I am inclined to doubt, he is promising.

YOUR correspondent puts two questions to me—one personal, the other typical. These I will endeavour to answer, then propound one which I hope he will answer in turn. The personal question is founded on the hypothesis that I may some day retire from work and live the life of luxury in a villa. I anticipate no such luck, but, on the contrary, am inclined to think that "Utilitarian," with his wages as a gardener and his commission as a trader, will first qualify himself for that distinction. Yet, suppose I should ever be able to retire into villadom, and attach a conservatory to my residence, I am invited to say what I should think if my assessment was increased on that account. I should think it quite right if it was not in excess, proportionately, of that of the Lord of the Manor. Conservatories are luxuries, and it is a fundamental principle of government administration that luxuries shall be taxed the first and the heaviest: necessities the last and the lightest. If I make a profit out of my conservatory the luxury is the greater to me, and the more enjoyed; therefore the assessment should be slightly increased; and if I add more structures, and especially if I profit by them, each should be rated in turn, because I am not dependant on them for a livelihood. That is my answer.

THE next question is typical. A garden of luxury, once well kept, is now practically abandoned through reduction and non-payment of rents, &c. I am asked to say why this neglected garden should not have its assessment reduced? If the estate of which the garden forms part is rated proportionately higher than the land and houses of farmers and market gardeners in the same parish, the assessment should be reduced; but if there is no such inequality, then, in my opinion, there should be no reduction, because this would amount to a contribution from impoverished farmers and others to maintain the "stables, showy men servants, and general keeping-up appearances," cited by "Utilitarian" as causes of neglected gardens. It would be granting a bonus for the very extravagance your correspondent condemns. If the garden were not amenable to improvement it would be another matter; but we are given an example of a garden being improved marvellously, yielding now a profit of £150, whereas two years ago it did not grow sufficient for the household. "Cultivation alone" gave the increased yield. That is the sound remedy. This garden is a greater luxury than ever, and if the assessment of the property is not already equal to that of surrounding market gardens, "Utilitarian" ought, as a just man, to be glad to see an early rectification.

NOW Mr. "Utilitarian," kindly attend to this. Supposing you have to leave your pleasant post, and have by frugality and thrift saved a few pounds, not sufficient for the "villa," but just enough to enable you to earn an honest living by hard work as a market gardener. Your little homestead is already assessed at as high a rate in accordance with the value of the property as the mansion and demesne you have left. You manage to erect a house, sell a crop of Cucumbers or Tomatoes from it

then, with the proceeds and a little borrowed money, erect another, so continuing your striving for a maintenance. How should you like Mr. Assessor to increase your rating with the increase of your stock, until your contribution became a hundred per cent. greater than that of your neighbour who is not dependant on the products of his garden for affording him the means to live? I cannot think you would like that, nor do I believe the owner of the mansion would like it if your positions were reversed; but, however, that may be, please answer the question as plainly as I have answered yours.

I SAY not one word against gentlemen selling garden produce. It is good for them to do so, for their gardeners, labourers, trade, consumers, and especially for "middlemen;" nor would I have them rated more highly than market gardeners are, any more than I would have these latter overweighted by local burdens. Given an equality in this respect, where would be the injustice? A grievance that is alleged to exist would be removed, as much "garden stuff" would be grown as ever, if not more, and the great mass of consumers in town would not have to pay one farthing extra in obtaining their usual supplies than they pay under existing circumstances.

IT is not necessary to refer to other points in the very interesting communication that I have been invited to examine, as I am mainly in accord with them, and I shall not be very much surprised if "Utilitarian" is not a little more in accord with my views in some other respects than appears on the surface, for I cannot help feeling that the full significance of his article is only to be grasped by reading between the lines; in fact, to speak exactly what I think, I must regard it as a skilful example of "drawing," as I see he tempts me on a larger question, but that bait is declined. I have been encouraged to proceed thus far because of the treat I am anticipating in the form of a (possibly crushing) reply.

I AM not able to give full assent to the opinions of "J. T. S.," which seem to imply that our dear old country will be bowled out of existence by foreign competition. I am fully convinced that nothing of the kind is in store for us. The advantages are on our side still if they can be turned to the best account. The "virgin lands" of the far north-west appear to cause some needless alarm. Land in America cannot be had quite for nothing. The rents of many farms that are rented in the west are as high as the reduced rentals of many a fertile—or might be fertile—farm in Britain. Hundreds of farms that are "owned" in America are worked with borrowed money, for which 7 or 8 per cent. interest is paid, labour is more costly there than here, while implements and manures are no cheaper. And what about "returns?" Flocks and herds do not command higher prices there than at home, while the average yield of Wheat in America is about 17 bushels per acre and in England nearer 27 bushels. With a margin like that in hand, and our competitors 5000 miles from market, I say it would be scandalous and humiliating for England to succumb.

LESS luxury, as in America, and better tillage at home; fewer hunting farmers and more enterprising energetic cultivators, with as much land as they can manage and no more; security for capital, freedom of cropping to the fullest extent possible, under necessary safeguards—given such conditions as these—and they are certain to come by degrees—the land of Great Britain will yield vastly more food than it produces now, and, though prices may be low, good livings can be had by those who will labour, and good rents will remain for the owners of land.

It is not the high prices that market gardeners get per dozen, or per bushel, or per cwt. for their wares, but the high culture they adopt, and the consequent great bulk of produce they obtain, that enable them to pay so much more rent than farmers pay. If they managed their land no better than thousands of acres are "farmed" at this moment, market garden rents would fall and tenants fail, for it seems that when rents, already moderate, commence falling, cultivators cease striving, as if in anticipation of the next abatement. It is time the truth was spoken on this subject, which is of vital interest to gardeners and everybody connected with or dependant on the land; and who is not? I feel I must apologise for occupying so much space. I quite intended resting for a week or two, but could not with propriety pay no regard to the admirable contributions to which I have referred.—A THINKER.

#### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE annual general meeting of the subscribers to this Institution took place Friday, January 15th, at "Simpson's," 101, Strand, when the report of the Committee and the accounts for the year were submitted. Happily the funds at command permitted the addition of twenty-five persons to the list of pensioners, the names being as follows:—John Andrews, of Astley Abbots, Bridgenorth, aged 60; William Elsworthy, of Wandsworth, aged 70; Frances Elizabeth King, of Salisbury, aged 62; Mary Ann Parker, of Southport, aged 70; Jacob Rose, of Stoke, Guildford, aged 62; James Snow, of Wandsworth, aged 66; Edward Spary, of Brighton, aged 82; William Archer, of Stratford, Essex, aged 81; Maria Austin, of Stourport, aged 68; Joseph Bellis, of Whitechurch, Salop, aged 68; Thomas Best, of Clapton, aged 70; William Cowles, of East Sheen, aged 68; Richard Daphne, of Ealing, aged 76; George Dawson, of Worcester, aged 73; John Dev, of Teignmouth, aged 67; Sarah Drummond, of East Sheen, aged 65; William Harman, of Denham, Uxbridge, aged 60; Elizabeth Howe, of Lowestoft, aged 67; Peter Lowe,

of Cheltenham, aged 67; Edward J. H. MacGuinness, of Gravesend, aged 73; Susan Mills, of Walthamstow, aged 78; Robert Pryor, of Brixton, aged 75; Joan Boyd Rintoul, of Manchester, aged 67; Eliza Skinner, of Cudham, Kent, aged 73; Sophia Ware, of Midhurst, aged 69. Thus increasing the number of pensioners from 104 in January, 1885, to 118 in January, 1886—viz., fifty-two men at £20 per annum, and sixty-six women at £16 per annum.

The following is the financial report for the year, which shows substantial and encouraging progress:—

Audited 11th January, 1886,

JOHN LEE,  
JOSEPH F. MESTON,  
JESSE WILLARD.

Referring to the above report the Secretary, Mr. E. R. Cutler, remarks:—"It is a curious fact, but it is a fact, that nearly all the other charities in London are curtailing their charity, and to make both ends meet are obliged to sell out their reserve. We are not only increasing our number of pensioners, besides increasing by 25 per cent. the amount of the pensions £4 per annum each, but we have increased our reserve to £21,000." The Institution now has permanent offices at 50, Parliament Street, S.W., to which all communications should be addressed.

#### THE PHYLLOXERA AND FOREIGN WINE AND BRANDY SUPPLIES.

WE hear of thousands of acres being devastated by phylloxera on the Continent, but we do not hear of any diminution in our wine or brandy supplies. Some very conscientious men have owned that supplies are short of certain kinds, but the general trader or wine merchant will readily undertake to supply any amount of wine or brandy supposed to be the productions of localities that are almost producing nothing in comparison to what they get the credit of. In this age of shams wines and brandies are freely tampered with, and the public are often made to swallow liquids that have not the slightest claims to the names and characters bestowed upon them.

From a report lately furnished to the Academy of Science by the head of the Paris Municipal Laboratory, it appears that genuine brandy is becoming exceedingly rare, even in France. "Chambers' Journal," commenting on this fact, states that "for the ten years preceding the year 1850 the quantity of alcohol distilled annually in that country averaged twenty-five million gallons, and the major part of this was obtained in the form of brandy from wine. Now, although the total amount of spirit distilled is more than doubled, the juice of the Grape does not contribute half a million gallons to the sum. The rest comes from grain, cider, perry, Beetroot, molasses, and Potatoes. This inferior kind of spirit is not properly rectified, and is charged with poisonous agents of the most deadly character. The compiler of this report, M. Girard, attributes the increase of insanity in certain localities wholly to these imitations of French brandy. Our readers may perhaps be ignorant of the fact that thousands of gallons of raw grain spirit are sent to France from this country to be doctored and returned as genuine French brandy."

Phylloxera seems to have broken out at the Cape, no doubt through the introduction of some wines from the Continent, and unless the authorities there are prompt in their efforts to cope with the dread pest we may expect to hear of much damage being done.—T. S. J.

In reference to this subject the following is an extract from the statistics published by the French Ministry of Agriculture:—

"The figures with regard to the vintage of last year are melancholy

reading for the producers—and, it may be added, for the consumers—of wine, as they show that the yield was the smallest, with one exception, known for the last thirty years, and 50 per cent. below the average of the last ten years, which have themselves been distinctly 'lean years.' The total amount of wine made was only 642,000,000 gallons, this being just a third of the exceptionally large crop of 1875. The decline is of course due in the main to the ravages of the phylloxera, as this insect has been so busy during the last ten or eleven years that the area of vineyards under cultivation has fallen from upwards of six to rather under five million acres, this alone telling plainly of the mischief that has been done. The cultivators of the Vine were further tried last year by the weather, which was very unfavourable for the Grapes, both in the summer and autumn, fierce drought preceding the rain instead of following it, and this was notably the case in the Bordeaux and Champagne districts, while the vineyards in the central departments of France, including the Burgundy district, were well favoured in the matter of weather. The mildew did a good deal of damage in the southern departments, but it is hoped that an effectual cure for this disease has been found in a solution of chalk and sulphate of copper, experiments upon a large scale in the Bordeaux district having been very successful. The departments in which the quantity of wine made was largest were the Hérault (48,330,340 gallons), the Aude (47,160,945 gallons), the Puy-de-Dôme (36,689,940 gallons), the Vienne (27,624,150 gallons), the Loir-et-Cher (27,414,045 gallons), the Côte d'Or (24,796,845 gallons), the Gironde (24,211,260 gallons), the Indre et Loire (22,572,990 gallons), and the Yonne (22,147,065 gallons). The only French departments in which no wine is made are the Calvados, the Côtes du Nord, the Finistère, the Manche, the Nord, the Orne, the Pas de Calais, the Seine-Inférieure, and the Somme, though in some of the others the yield is very small, notably in those which, like the above-named, are nearest to the British Channel. Small as was the crop of wine last year, the quality is reported to be remarkably good, and the prices are said to be going up; but the situation is none the less a very unsatisfactory one, for the imports of wine into France last year were over 180,000 gallons, or equal to more than a third of the whole quantity made in France. Worse still, the exports of wine were only 55,575,000 gallons, while ten years ago the exports were 81,767,500 gallons, and the imports only 6,000,000; that is to say, the imports have increased in the proportion of thirty to one while the exports have decreased at the rate of three to two."

THE annual general meeting of the ROYAL HORTICULTURAL SOCIETY will be held in the conservatory at South Kensington on Tuesday, February 9th, the chair to be taken at 3 P.M. The first annual dinner will be held the same evening at 6.30 P.M. at the Criterion, and not at the Albion as was previously noted.

— MR. SHIRLEY HIBBERD has withdrawn his name from the list of officers of the INTERNATIONAL POTATO EXHIBITION, and will not in future be associated with the proceedings.

— A CORRESPONDENT, "G.," asks if any of our correspondents can inform him as to "the best seed drill suitable for market gardening."

— MR. J. GADD, Belhus, Aveley, writes—"As opinions are solicited respecting READING HERO POTATO, I may confidently say as far as my knowledge goes that it is good in quality, a good bearer, of strong constitution, and will become in this neighbourhood the Potato for the general crop both with market growers and cottagers."

— WE are informed that at the DEVON AND EXETER HORTICULTURAL SOCIETY'S 1886 Summer Show, Friday, 20th August, and Autumn Show, Friday, 12th November, the Trustees of the Veitch Memorial Prize Fund have allotted a Veitch Memorial medal and a prize of £5 for competition at Exeter in 1886, the competition to be confined to the County of Devon. The Committee of the Devon and Exeter Horticultural Society have resolved that the medal and prize shall be given for a collection of vegetables, to be competed for at their Summer Show (20th August). Schedules and further particulars can be obtained of the Hon. Secretary, C. T. K. Roberts, Esq., 15, Gandy Street, Exeter.

— A NEW American periodical entitled the "HORTICULTURAL ART JOURNAL" (Mensing & Stecher, Rochester, New York) was announced some time ago, and the first part has just reached us. It is to be published monthly, giving eight pages of matter and four coloured plates

of flowers and fruits. Those in the first part represent the following— Marshal P. Wilder Rose, a seedling from Général Jacqueminot, which first flowered in 1881; Plum, Shipper's Pride, a dark purple free-fruited variety; Rancocas Raspberry and the Niagara Grape, a white variety which is said to be very hardy, enduring "a temperature 35° below zero." These plates are well executed, and the general appearance of the publication is satisfactory, but we regret that as regards literary honesty the publishers have commenced badly. A slightly reduced reproduction of our block representing Whinham's Industry Gooseberry, which was engraved for this Journal, and appeared on page 253, September 17th, 1885, is given in the last page of the periodical under notice without a word of acknowledgment.

— "W. O., Fota Island, Cork," writes—"It may not be generally known that *Physianthus albens* is quite hardy in the south of England. Plants raised from seed have grown 20 feet high in four years, bearing its small white flowers and numerous large seed pod. The plant will grow in any moderately light rich soil, and is easily raised from seed. A plant here on a south-east wall has been in flower for several months. The flowering at this season I attribute to the dry hot summer of 1885."

— THE sixth annual general meeting of THE ESSEX FIELD CLUB will take place at the Public Hall, Loughton, Essex, on Saturday evening, January 30th, 1886, at half-past six o'clock. The report of the Council for the year 1885, and the Treasurer's statement of accounts, will be read and submitted to the meeting. The election of new members of the Council and Officers for 1886 will also take place. An ordinary meeting will also be held solely for the proposal and election of new members. The annual presidential address will be delivered by T. Vincent Holmes, F.G.S., M.A.I., the subject being "Notes on the Evidence Bearing upon British Ethnology."

— HINTS TO POTATO GROWERS.—One of the largest Potato salesmen in the country writes as follows to the *North British Agriculturist* regarding the culture of the favourite esculent:—"Potatoes are very plentiful, and, in spite of what was written about short crops and heaps of statistics and tabulated business, there are as many Potatoes in Great Britain as there were last season. The only fault is, however, more prevalent than ever, black when cooked. Four-fifths of the Potatoes in the market are Magnum Bonums, and nine samples out of every ten cook more or less black. This may seem exaggerated, but it is a fact; some are so black as to be nearly useless. I think, taking them all round, the Scotch Champion cook best this season, and some of the blackest are off the best warp lands of Yorkshire and Lincolnshire, where we should have the very finest quality. All Magnum Bonums in south, home, and midlands are full of second growth. I expect a great lot of Regents will be planted next season. They have done well in Scotland especially; no blight at all, good shape and quality, and good crops, but they are all consumed in local and north of England markets, where they will not have Magnum Bonums while they can get round Potatoes, and they are not bad judges, but in London and south they will have Magnums. It's strange, but true. There are a good many Magnums going from Scotland just now to New York, where they are at present worth £6 to £6 10s. per ton, but the heavy duty and charges there reduce the nett result very materially. The duty is over £1 per ton. So, although the American growers have small crops, they are making fair prices on account of the prohibitive duty. It is very different here. There are lots of German Potatoes here; the freight of about 6s. right up to the river side wharves from Hamburg has induced the Germans to send, but there is no trade for them. The freight from Holland is about 7s., from France 6s., from other places as low or lower, so our farmers in the north have a good chance against this, paying 13s. to 16s. from Yorkshire, 20s. from Cheshire, and 25s. to 30s. from Scotland. Many from Yorkshire are coming this season by sailing vessels, and, of course, from Scotland, but this can only be done where Potatoes are near a river or sea coast."

— AT the ordinary weekly meeting of the PAXTON SOCIETY, held at Wakefield recently, Mr. Henry Oxley, one of the Vice-Presidents, occupied the chair, and Councillor Milnes was in the vice chair. Mr. J. Smith, gardener to Mr. T. Green, of Leeds, read an excellent paper entitled, "Historical Introduction to Rudimental Botany." The essayist was listened to with the greatest attention, and at the close of his paper he was, on the motion of Mr. T. Garnett, seconded by Mr. L. Twigge, accorded a very hearty vote of thanks. The lecturer exhibited a large number of

beautifully mounted and named botanical specimens which he collected and mounted seventeen years ago, and they were much admired. At a subsequent meeting, Mr. T. Garnett, gardener to Miss Mackie, St. John's, gave "An Essay on the Potatoe Disease." The lecture was an admirable one throughout, giving the whole history of this destructible disease. The Fungi was shown in its various stages by the aid of three powerful microscopes, and Mr. Garnett had prepared a number of diagrams also showing the development of the "Peronospora" very much enlarged. After a lengthy discussion having special reference to the way of destroying the spores and otherwise checking the ravages, the usual vote of thanks was heartily passed to Mr. Garnett.

— WE welcome a new contemporary which has just appeared under the captivating title of *Fishing*. As its name implies, its pages are devoted to papers on angling and information on all angling matters. The papers are admirably written and are most entertaining, not to anglers only but to others who relish literary leisure. The first number is illustrated by an excellent chromolithograph of a Thames barbel, and also with various other illustrations interspersed in the letterpress. It is issued from the office of *Land and Water*, and we wish it success.

— THE following prizes "open to all England" will be competed for at the ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY'S SHOWS for the current year:—June 29th, nine stove or greenhouse plants (in flower), £10, £8, £5; six Cape Heaths, £4, £3, £2; twelve Pelargoniums (not Fancies), £4, £3; twelve ditto (Fancies), £4, £3; twenty-four Roses, distinct (single trusses), £2, £1 10s., £1; twenty-four ditto (in triplets), £3, £2, £1: Webb & Sons' Special Prizes—Six dishes of vegetables, distinct £3 3s., £2 2s., £1 1s., and 10s. 6d. July 29th, Sutton and Sons' Special Prizes—Six dishes of vegetables, distinct, £3 3s., £2 2s., £1 1s., and 10s. 6d.

— A CORRESPONDENT writes:—"At one of the meetings of the National Society of Horticulture of France last year M. George Chemin, market gardener of Issy, was awarded a prize for his exhibit of TOMATOES of a large red variety, of which eighteen weighed a trifle over 17 lbs. The variety is commonly cultivated by Parisian gardeners, but it is by exceptional carefulness of cultivation that these were brought to such rare beauty, and not only on exceptional plants but uniformly. One part of the treatment deserves mention; it consisted in wetting them thoroughly every morning to prevent their cracking with the first rain, and the result was seen to be most satisfactory."

— WE learn with regret that FRANCIS ERSKINE LAING, aged twenty-two, the youngest son of Mr. John Laing, died at Stanstead Park, Forest Hill, after a painful and protracted illness.

— AT the annual meeting of the PUTNEY AND DISTRICT CHRYSANTHEMUM SOCIETY, held on the evening of the 21st inst., the Honorary Secretary, Mr. J. Moore, was surprised by the presentation by Mr. Pitt of a handsome walnut stationery cabinet completely furnished; also with an address from the members, thanking him for his services to the Society. All who know Mr. Moore will acknowledge his unfailing courtesy, also his disposition to do well whatever he undertakes, and this recognition of his services is well merited. The next show of the Society is fixed for November 16th and 17th.

— A CORRESPONDENT, "A. B. C.," desires information on GARDENING IN AUSTRALIA. He wishes to know, "What prospects are there for gardeners emigrating and finding situations similar to those in England? also for market gardeners and nurserymen?" We will readily publish information on this subject that any of our readers may be able to supply.

— THE NATIONAL CHRYSANTHEMUM SOCIETY held their annual general meeting on Monday, the 25th inst., at the Old Four Swans, Bishopsgate Street. The principal business was the election of officers and General Committee for the ensuing year. The officers of the past year were re-elected—namely, President, Mr. E. Sanderson; Vice-President, Mr. R. Ballantine; Treasurer, Mr. J. Starling, and Hon. Sec., Mr. W. Holmes. Several members were added to the General Committee comprising Messrs. G. S. Addison, N. Davis, H. Cannell, G. Gordon, L. Castle, G. Stevens, E. C. Jukes, J. W. Springbett, and C. Harman Payne. The balance sheet showed that the finances are in a satisfactory condition, and it is proposed to hold a September Show for the early-flowering varieties of Chrysanthemums. Mr. W. H. Cullingford has liberally contributed ten guineas towards another late exhibition in

January. The election of members to form the Floral Committee was referred to the first meeting of the General Committee.

— THE annual meeting of the HUDDERSFIELD CHRYSANTHEMUM SOCIETY was held on Saturday evening last, at the Queen Hotel, under the presidency of Mr. G. Jarman. It was stated that they commenced last year with a balance in hand from the previous show of £63 10s. 10d. They thought they were entitled to offer some good prizes, so as to induce some of the best growers in the country to compete, and accordingly prizes to the value of £105 were offered. The season, however, turned out very unfavourable for the Chrysanthemum in that part of the country. A hot summer was succeeded by a cold August, and the blooms were not in such a good state as could be desired. Nevertheless, the exhibits were excellent, and the Judges, who were experienced men, said they were as fine as they had seen anywhere, north or south. Although the balance is not so large this year as last, it was readily accounted for by the fact that the previous year being the first year a special effort was made, and some people subscribed larger than they meant to continue. The total income, including a balance of £63 10s. 10d., came to £244 17s. 6d., and the total expenditure to £167 12s. 8d., leaving a balance in hand of £77 4s. 10d. It was decided to hold the third annual show on Friday and Saturday, November 12th and 13th next. The Mayor (Alderman J. Varley) is to be requested to act as President of the Society during the year, the Vice-Presidents being increased by the addition of the names of Mr. S. Learoyd, Mr. J. Hey, and Mr. G. E. Elliott. Mr. George Jarman was re-elected Chairman of the Committee of Management, Mr. G. W. Rhôdes being appointed Vice-Chairman, and the following Committee was elected:—Messrs. W. Daniels, H. Hillman, M. Chambers, F. Stokes, F. Carter, W. Tindale, G. Barr, C. Smedley, J. Nettleton, J. W. Thornton, F. Hutch, J. Burns, T. Baxendale, J. Smith, George Hey, J. Sykes, W. Matthewman, E. Newsome, W. Swindlehurst, T. Stephenson, W. Heywood, J. Beaumont, J. Bulb, B. Mickelthwaite, G. Pownoy, and W. Ferguson. Mr. W. B. Hill was re-elected Treasurer, and Mr. John Bell Hon. Secretary of the Society.

— KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.—The Committee met on Tuesday evening to draw up the schedule of prizes for 1886. It was unanimously resolved to offer another twenty-five-guinea challenge cup on the same conditions, and with money prizes as before—viz., first prize, cup and £5; second, £4; third, £3; and fourth, £2, for forty-eight cut blooms distinct, twenty-four incurved, and twenty-four Japanese; and, in addition to other extra-monied and special prizes, there is offered for the first time a silver cup valued £5 for the best group of Chrysanthemums 50 feet, and second, third, and fourth prizes of 70s., 50s., and 30s. respectively. There is also offered a local cup for twenty-four cut blooms, twelve incurved and twelve Japanese, of the value of £5, with a second prize of £3, and a third of £2, open to all subscribers within the Kingston Poor Law district. Mr. F. A. Davis having resigned the Presidency, Mr. Alderman G. C. Sherrard has been unanimously elected President of the Society.

— "SLOUGH" writes:—"Can 'Thinker' or any other correspondent suggest a remedy for the 'CLUB,' with which our Broccoli have been affected every year? The soil is gravelly loam resting on gravel. I have tried without success puddling the roots in clay, planting in undug ground, and in ground into which had been mixed 1 bushel of lime to 1 perch, also both early and late planting. Last year the disease was worse than ever. Would coal ashes be conducive to the spread of the disease?"

#### GROS COLMAN VINE.

I DO not wonder that the "potash theory" advanced by Mr. Taylor on page 576 of the Journal for Dec. 31st in reference to this Vine has arrested the attention of Grape growers. It is a subject of vital importance, and I trust it shall receive from the hands of our scientific horticulturists the attention it deserves. I believe the absence, or at least an insufficient supply of something in the soil, has more to do with the tenderness of the foliage of this variety than most people imagine. What that is I am not prepared to say; that I will leave our scientific friends to discover.

Last October, while visiting the gardens of a gentleman in this neighbourhood, a remarkable circumstance was brought under my notice, which has a forcible bearing on the subject at issue. In a small vinery Lady Downe's, Alicante, and Gros Colman, growing side by side, and receiving exactly the same treatment, displayed the most unusual diversity of foliage. The Lady Downe's had certainly nothing peculiar about it, but much like what we usually see in the month of October. The leaves were just beginning to take on their autumn tints, but the Alicante—there was but one rod—presented a truly remarkable and magnificent appearance, every leaf being of a bright crimson colour, not blotched or

striped, as is sometimes seen, but one mass of colour and perfectly fresh. I have known some varieties produce the most lovely tints while ripening, but never any to approach the grandeur of this blood-red Alicante. I was informed that it had displayed this peculiarity for many years, and that its leaves were much sought after for house and table decoration, which when dried and varnished would be most useful and attractive. By the side of this Alicante was a rod of Gros Colman, every leaf of which was as green and fresh as if it had been midsummer. It was carrying a very fine crop of large bunches with extra large berries, and perfectly black. The vinery was a lean-to and facing the south, built of iron, the sashbars and astragals being of the lightest description, with large panes glazed without putty. So this Vine of Gros Colman was fully exposed to the full blaze of the sun during the past bright summer, and yet in the month of October its foliage was in this high state of preservation. Doubtless the mysterious something which coloured the foliage of the Alicante was the means of preserving the foliage of the Gros Colman. What that something is would be most interesting to know.—D. B.

MR. TAYLOR replies to "A. L. G." briefly, and I am sorry to find he gives me the option of supplying scientific information which Mr. Taylor himself hesitates to put on paper. I have no desire to be considered a competitor on this point with the founder of the famous Vines at Longleat, from which I was kindly favoured with some eyes a few years ago. Appreciating Mr. Taylor's spirit in discussions, I am willing in the capacity of pupil to state my mode of making and using potash, which is carefully prepared wood ashes, containing on analysis a good proportion of potash. When we dress Vine borders during winter part of the surface is removed in the usual way, and in some case pointed with a piece of sharp iron, but our early Vines especially have now become such a mass of fibre on the surface that any interference seems cruel. A very heavy layer of wood ashes is spread over the border, next follows a layer of loam and old lime rubbish, and then a covering of newly shaken out droppings, as for Mushroom culture. This being done, a thorough watering is given, and allowed to settle a couple of hours, when another thinner covering of wood ashes is given, the large flat river stones are replaced, paving the border, and a moderate watering is supplied.

Mr. Taylor seems to think it difficult to understand why shade is needed by Gros Colman more than other Vines. My observations leave little doubt regarding this point—at least, in our case; and as Mr. Taylor has succeeded in growing Gros Colman satisfactorily without shade there may be some difference in the structures, or the distance of the Vines from the glass. If, as at Longleat, Mr. Taylor's Vines are some distance from the glass, which is not the case here, ample compensation for shading would be afforded. As "Thinker" remarks, however, there is considerable difference in the foliage of Gros Colman as compared with others. This, coupled with the greater amount of veinless surface, and the fact that the leafstalks detach more readily from the wood in any stage of growth than others, convinced me that some special treatment of the foliage was necessary. Further examination this winter has shown that Gros Colman has not so many surface roots as some other Vines, Trebbiano in the same house having quite treble the amount of fibre. If such should be universal some degree of failure to retain its foliage might result from lack of root-action, and any neglect in watering would as a consequence be sooner felt.

I fear I do not rightly comprehend Mr. Taylor's meaning when he says that a good leaf of Gros Colman is double the thickness of any other variety that is now usually grown in houses. I have never seen it thicker in texture than some others. I may add that during July last summer we removed the large stones from our Vine borders and placed about 5 inches thickness of newly scythe-mown grass in a wet state, again replacing the stones and giving a thorough soaking with diluted liquid manure washed from a large heap, cow and horse manure mixed. On removing the stones white fibrous roots in abundance were found underneath them, and in five weeks they had penetrated and fairly taken possession of the green ensilage-like food, and underneath the stones again becoming matted. I need hardly say a great improvement was visible.—LATHYRUS.

"A THINKER" certainly deserves credit for his latest discovery—"the microscopical thought," and the note from his botanical friend as to the arrangement of the cells in the leaf of this Vine is interesting and suggestive. There is no doubt, as your correspondent says, that Gros Colman, and also other varieties of Vines, would often do better if they had as much water as they required. But before we make up our minds that this variety does need an appreciably larger quantity than others we must have further evidence.

If Gros Colman evaporates more water from its foliage it will follow that it will dry more quickly at the root; and if this or any other variety suffered from lack of water sufficiently to cause the injury I mentioned at page 576, it would not recover sufficiently in one season to produce Grapes fit for the exhibition table the next year. When I say that the Vines alluded to were grown by myself in 1884, and that they included those which bore the Muscats shown in Bath in September, 1885, so highly eulogised by Mr. Coleman at the luncheon as the best Grapes in the exhibition, and also by your special reporter, as probably the best Muscats that had ever been grown in pots; and further, that two bunches of Gros Colman shown at the same time off one of the Vines that suffered the most was pronounced by your reporter to be the blackest he had ever seen of that variety, it will go some way towards proving that the lack-of-water theory will not apply in this particular case. Whether Gros Colman needs more water than other varieties can scarcely be tested practically when it

is planted amongst others in a border; but when grown in pots it can be readily tested.

In this case I happen to know that Gros Colman took and required less water than the others during part of its growth; but I will explain that that fact cannot be used against your correspondent's argument. As I have before stated, its foliage was the first to become discoloured, and it suffered more than any other variety for the lack of something. Then, as a matter of course, it could not evaporate the water so fast, and when I did not apply the water myself I invariably tested the pots, and those containing Gros Colman were many times marked by placing a stick in the soil as a reminder to my deputy that they were not to be watered. This is, of course, fixed on my memory. I cannot say whether they took more water than others during their healthy condition, but I certainly am under the impression that I should have noticed it if they did.

"Thinker" says "If the absence of potash alone is the predisposing cause of the collapse of the foliage, how is it that shaded leaves continue fresh the longer?" As well ask how can a man who never used his muscles, and is never exposed to unpleasant weather, he preserved to look well till he reaches the age of threescore? To look at, he appears as good as another man; but appearances are misleading, both in men and foliage.—WM. TAYLOR.

### THE PLANTING OF THE FITTEST.

SHOULD anyone when the weather is favourable (for it will even then not be too late to set fruit trees, since the sap must still be dormant) have a spare corner in garden, field, or orchard for another Apple tree or two, let him try Bramley's Seedling. The tree is very hardy in growth and good in habit; fruit certain, beautiful, and profitable. Bramley's Seedling is not as well known as it might be. The Apple is large, round in shape, eye full and deep set, colour in swelling a peculiarly intense green, changing as it ripens to soft yet brightest, fullest red, diffused flush-like more or less all over the fruit, and, unlike other high-coloured Apples, having nothing of that hardness in appearance which resembles painted or waxen imitations.

Bramley's Seedling ripens in October, is good for table, excellent for cooking, hard-fleshed, white inside, and with common care can be kept for months. On fruit-storing, though so late, I should like some time to say a word or two which might be helpful.

The weather has been severe, with heavy snow from the north. In my notes last week "growing Poppies" should have been "growing Poppies."—A. M. B., *Mid-Lincoln*.

### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 39.)

NUMBER OF PLANTS REQUIRED TO GIVE BLOOMS IN FORTY-EIGHT, TWENTY-FOUR, AND TWELVE VARIETIES.

YOUNG growers are often much puzzled to know how many plants they should cultivate with the intention of having a given number of exhibition blooms at a certain date. Many persons think it right to grow a very large number of varieties, but in this case the old adage, "Safety in numbers," does not apply; quite the reverse. It is far better to select a fixed number of varieties best suited for the purpose intended, growing a number of plants of each, than to be burdened with a host of kinds that cannot be relied on for the object in view. Several varieties are admittedly useful for other purposes than supplying exhibition blooms of the highest quality; but if the production of these is the main point, varieties that do not afford them should be eschewed. I strongly advise all who have not had experience to bear in mind when forming collections that variety may have charms, but not in all cases value.

If an exhibitor wishes to stage forty-eight distinct blooms, twenty-four of which may be incurved and the remainder Japanese, he should grow at least thirty-six varieties in each section, as all are not to be depended upon to produce what is required. In some seasons one sort is quite useless, whereas the next year quite the reverse may occur. Casualties, too, may happen during the season of growth quite unexpectedly, such as shoots being broken at a critical period by wind, and other unforeseen circumstances; therefore not less than the number stated should be depended upon to insure success. These should consist of the very best, as named in the list previously given. It will be necessary to have 300 plants to effect the object in view, or 150 in each section. In the twenty-four class, supposing them to be half incurved and the remainder Japanese, twenty-four varieties in each section are not too many to grow, and the total number of plants should not be less than 150. When confined to a smaller class of, say, twelve distinct, either Japanese or incurved, the selection should be more rigid than in the larger classes, as there is not so much margin allowed for an inferior specimen or two in smaller, where all are expected to be of the first merit. Twenty-four names should be chosen, and about seventy plants grown, giving the preference to those named in the first part of my list in each section.

To afford blooms for a stand of twelve varieties the selection should be rigorously made (even more so than in the large classes)

selecting those kinds which are known to be the most certain producers of fine flowers. In competing in a class for twelve blooms, either Japanese or incurved, the general good quality should run right through the stand, as in such small classes there is not that opportunity to insert a moderate bloom or two like there is in larger classes. For the benefit of inexperienced growers I append a list of the best twenty-four kinds in each section and the number of each variety it would be advisable to grow for the purpose named :—

**TWENTY-FOUR VARIETIES JAPANESE.**—Four Madame C. Audiguier, four Belle Paule, three Fair Maid of Guernsey, four Jeanne Delaux, three Baron de Prailly, four Criterion, four Val d'Andorre, three Meg Merrilees, three Boule d'Or, three Marguerite Marrouch, three Comte de Germiny, three M. Ardene, three M. Burnet, two Hiver Fleuri, two Thunberg, two M. Astorg, two Elaine, three Duchess of Albany (Jackson), two Japonaise, three Fernand Feral, three Golden Dragon, two Peter the Great, two Sceptre Toulousain, three Mlle. Lacroix.

**TWENTY-FOUR VARIETIES INCURVED.**—Four Lord Alcester, four Empress of India, four Queen of England, four Golden Empress, three Golden Queen of England, four Alfred Salter, three Princess of Wales, four John Salter, two Lord Wolseley, three Prince Alfred, three Jeanne d'Arc, four Hero of Stoke Newington, three Jardin des Plantes, two Mrs. Heale, three Princess of Teck, two Refulgence, two Mr. Bunn, two Empress Eugénie, three Mrs. W. Shipman, two Lady Hardinge, two Lady Carey, two Sir Stafford Carey, three Barbara, two Cherub.

#### MANAGEMENT OF YOUNG PLANTS.

This is a very important phase in the cultivation of the Chrysanthemum, as upon the treatment they receive in the early stages their future welfare depends. Especially they should not be checked in any way, or they will be stunted. When the plants are well rooted and will bear free exposure to the air without flagging remove them from the handlights and place them upon a shelf close to the glass in the same house where they were struck. The advantage of a light position is that it prevents their becoming weakly. They also get more air than they can have when placed on the side stages of the house if ventilation can be given at the top of the house. If the house is not provided with shelves temporary ones can easily be put up by suspending them from the rafters by means of strong wire and screws. The shelves may be about 9 inches wide, according to circumstances, and on each side there should be a groove to run the water off to one end, which can easily be done by allowing a slight slope in fixing the shelves. Any plants standing underneath the Chrysanthemums are then not splashed by the water given to the plants overhead.

At this stage I prefer a cool house to a cold frame for the plants for the same reason as explained in the case of cuttings—that less trouble is caused in preserving them from frost and allowing them exposure to light; but the house must be kept perfectly cool—just enough heat to prevent the plants being frozen. In such a house the air can be maintained in a drier condition than in a cold frame, and mildew, which frequently attacks the young plants, can be more easily dealt with. Great care should be exercised in supplying water, never allowing the soil to become dry.

The future object of the plants must be now determined. Those that are intended to be grown for the production of cut blooms or groups will not require stopping. When the pots are well filled with roots, and before they become root-bound, they will require larger pots. At this time the size in which they are to bloom must be taken into consideration, and for the bulk of the varieties 9-inch pots are large enough, and then the first shift from the cutting pots should be into those 3½ inches wide. The next time employ pots 5½ inches in diameter, and transfer the plants from these to the 9-inch pots. If growers desire to use larger pots, say those 10 inches in diameter, 4½-inch pots should be used at the first shift, next 6½-inch size, and then the 10-inch pots. Where pots of 10½ and 11 inches are in stock I prefer placing two plants in each in preference to potting them singly, using the weaker-growing sorts. By this means a great saving in space is effected, as nearly double the quantity of plants can be grown in the same space. To prepare the plants for these pots at the first shift they should go into the 3½-inch size and then into the 5½-inch size, which allows them to be the right size to occupy the 11-inch at the final potting. As the “cast” sizes vary at different potteries I think it better to give the sizes in inches, always measuring inside.

The soil used for this first potting should consist of two parts fibry loam, one part leaf soil, and one part of spent Mushroom bed materials, with a free admixture of sharp silver sand; if the loam is inclined to be heavy add crushed charcoal freely, which keeps the whole porous. For the greater convenience in potting pass the compost through a coarse sieve, rubbing the fibrous pieces through

also; the pots must be quite clean and carefully drained; over the crocks place some of the rougher parts of the soil and pot firmly. If the soil is moist when used no water will be required for a day or two; after this time they must not be allowed to suffer by want of it, neither must they have too much. Return them after potting to their former position on the shelves till the roots run through the soil to the sides of the pots; place a neat stake to each and transfer them to a cold frame or pit, standing them upon ashes near to the glass. Keep the frame rather close for a day or two, avoiding draughts, after which admit abundance of air according to the state of the weather. On very fine days take the lights off for a time, as by this means the plants are kept “stocky.” As soon as the pots are filled with roots they are ready for their second shift as described, the soil consisting of the same materials as at the last potting, with the exception that fine ground bones can be added freely, and a 5-inch potful of soot to 4 bushels of soil, potting the plants more firmly than previously.—E. MOLYNEUX.

(To be continued.)

#### ORANGE CULTURE.

IN 1866 my father read a paper on “Dessert Orange Culture” before the members of the Horticultural and Botanical Congress then assembled. He had successfully cultivated Oranges for some years, and had formed a collection of several kinds. The house which he there describes is still used for the same purpose, some of his fruiting trees being still in existence. When the simplicity of Orange culture is known, it is likely to be more popular than it is. An Orange house is charming in December and January, and, unlike an Orchid house, can be thoroughly enjoyed, the temperature being very agreeable, as it need not be higher than 50°; the rich dark green of the leaves contrasting with the golden fruit appealing equally to the eye and the palate, the fruit being delicious when thoroughly ripe. I prefer half-standard trees to those trained on walls, a double row of trees in a span-roof of 100 feet being a picturesque sight. The cultivation and pruning are simple enough, the most exacting work being the destruction of scale; moderate and careful attention will, however, effect this. If any of your readers take an interest in the cultivation of this delightful tree, they should procure the Horticultural Congress papers by Thomas Rivers of Sawbridgeworth—T. FRANCIS RIVERS.

#### TWO RARE PITCHER PLANTS.

NEPENTHES EDWARDSIANA AND N. VILLOSA.

NEPENTHES villosa and N. Edwardsiana are found growing on the great mountain of Kina Balu in North-Western Borneo, and together with N. Rajah and N. Lowii, were long ago figured by Dr., now Sir Joseph Hooker, in vol. xxii. of the Transactions of the Linnean Society of London. These fine illustrations were copied, of a reduced size, and coloured in St. John's “Life in the Forests of the Far East,” vol. i., a book which all who are interested in Borneo should read.

Speaking of these plants, St. John, vol. i., p. 334-5, says, “As we ascended [Kina Balu] we left the brushwood and entered a tangled jungle in which few of the trees were large. The spur of the mountain became very narrow, sometimes not much wider than the path, and was greatly encumbered at one part by the twining stems of Nepenthes Edwardsiana. This handsome plant was not, however, much diffused along the spur, but confined to a space about a quarter of a mile in length and it clambered upon the trees around with its fine pitchers hanging from all the lower boughs. We measured one plant, and it was 20 feet in length, quite smooth, and the leaves of a very acute shape at both ends. It has a long, cylindrical, finely frilled pitcher growing on every leaf. One we picked measured 21½ inches long by 2½ in breadth. They swell out a little towards the base, which is bright pea green, the rest of the cylinder being of a brilliant brick-red colour. Its mouth is nearly circular, the border surrounding it being finely formed of thin plates about a sixth part of an inch apart, and about the same in height, and both of a flesh colour. The handsome lid is of a circular outline. The dried pitcher forwarded to Dr. Hooker only measured 18 inches. The plant is epiphytal, growing on Casuarinas (species nova). The pitchers of the young creepers precisely resemble the older ones, except in size.” It is to be hoped that this splendid plant will be introduced by some of the explorers of the new North Borneo Company, in whose territory this great Pitcher Plant mountain stands.

N. villosa is found at an altitude of from 9000 to 10,000 feet, and is a strong-growing terrestrial species with rounded pitchers densely covered with short hairs. The rim and lid of the urns resemble those of N. Edwardsiana, but the swollen or lower part of the pitchers are of a lovely rose colour, not unlike that of a well-ripened Royal George Peach in colour, but a little rougher in texture. The largest pitchers are about 5 inches long by 4 inches broad.

The five days journey from the N.W. coast to this mountain is by no means an easy undertaking, and unless the explorer should time his journey so as to be on the spot just as the Nepenthes are at their best stage of growth for removal, his chances of introducing these noble plants alive to Europe is of the most remote kind.

It is pleasant to know that the life history of these most interesting plants has lately received the most successful attention of Dr. Macfarlane | that Mr. W. E. Dixon has in preparation an elaborate historical paper on this interesting family, the publication of which is awaited with much

Fig. 12.—*NEPENTHES VILLOSA* AND *N. EDWARDSIANA*.

of the Botanical Gardens, Edinburgh, where also Mr. Lindsay has reared | interest. As will be seen from the above careful measurements, our many distinct hybrids of botanical interest; and lastly I am glad to know | illustrations (fig. 12) are considerably below the natural size. The

pitcher on the left hand is *N. villosa*, that on the right *N. Edwardsiana*.—F. W. B.

### ROYAL METEOROLOGICAL SOCIETY.

THE annual General Meeting of this Society was held on Wednesday evening, the 20th instant, at the Institution of Civil Engineers, Mr. R. H. Scott, F.R.S., President, in the chair.

The Secretary read the report of the Council, which stated that the past year had been one of great activity, as the eight Committees which had been appointed had met frequently, and had done much for the advancement of meteorology. The number of Fellows on the roll of the Society is 537.

The President (Mr. R. H. Scott), in his address, said that as he had treated of land climatology in his previous address, he proposed to deal with marine climatology on the present occasion, and to take up the subject at the point where he had left it in his paper, "Remarks on the Present Condition of Marine Meteorology," printed in the Society's "Quarterly Journal" for 1876. He enumerated the various investigations which had been announced to be in progress at that date, and specified the several outcomes of these inquiries which had seen the light during the ten years. The "Meteorological Charts for the Ocean District Adjacent to the Cape of Good Hope," published by the Meteorological Office in 1882, was first noticed, and the methods of "weighting" observations of wind, &c., employed in that discussion were fully explained, as well as the mode of representation of barometrical results. The "Charts Showing the Surface Temperature of the Atlantic, Indian, and Pacific Oceans," published in 1884; and those of barometrical pressure, now in the engraver's hands, were next noticed, and it was announced that the Meteorological Council had decided to undertake the issue of Monthly Current Charts for the entire sea surface. The Wind Charts, published by the late Lieut. Brault of the French Navy, were next described, with an expression of the profound regret with which the intelligence of his premature death in August last had been received by all meteorologists. The Wind Charts and Pressure Tables issued by the Meteorological Institute of the Netherlands were then explained, and also the publications of the Deutsche Seewarte at Hamburgh—"The Atlas of the Atlantic Ocean," &c. The series of "Monthly Charts for the Atlantic and Pacific Oceans," issued by the Hydrographic Office, Washington, were then described, and the present series of "Pilot Charts," issued by the same office were explained.

As for projected work in 1886, Mr. Scott stated that the daily maps of Atlantic weather for the year of the circumpolar expeditions were now complete, and were being engraved, a process which must take several months. The German Office had undertaken the preparation of daily weather maps for the same period for the South Atlantic. The Meteorological Office had also taken up the marine meteorology of the Red Sea. The Dutch Institute had announced its intention to publish an atlas for the Indian Ocean.

In conclusion, Mr. Scott stated that there still existed a lamentable want of data for the Pacific Ocean, but that, thanks to the energy of the Canadian Government in opening up their new Pacific Railroad, it was to be hoped that every year would bring a greater amount of traffic to British ports on the Pacific coast, and, therefore, a greater number of observations to the Meteorological Office; while from the existing trade to San Francisco a mass of materials was quickly accumulating, for certain routes at least, over the vast area of the Pacific.

The following gentlemen were elected the officers and Council for the ensuing year:—President, William Ellis, F.R.A.S. Vice-Presidents, George Chatterton, M.A., B.Inst.C.E.; Edward Mawley, F.R.H.S.; George Mathews Whipple, B.Sc., F.R.A.S.; George Theodore Williams, M.A., M.D., F.R.C.P. Treasurer, Henry Perigal, F.R.A.S., F.R.M.S. Trustees, Hon. Francis Albert Rolfe Russell, M.A.; Stephen William Silver, F.R.G.S. Secretaries, George James Symons, F.R.S.; John William Tripe, M.D., M.R.C.P.Ed. Foreign Secretary, Robert Henry Scott, M.A., F.R.S., F.G.S. Council, Edmund Douglas Archibald, M.A.; William Morris Beaufort, F.R.A.S., F.R.G.S.; Arthur Brewin; Frederic William Cory, M.R.C.S.; Henry Storks Eaton, M.A.; Charles Harding; Richard Inwards, F.R.A.S.; Baldwin Latham, M.Inst.C.E., F.G.S.; John Knox Loughton, M.A., F.R.G.S.; William Marcet, M.D., F.R.S., F.C.S.; Cuthbert Edgar Peek, M.A., F.R.A.S., F.R.G.S.; Captain Henry Toynbee, F.R.A.S.

### MILDEW ON ROSE TREES.

I AM glad to see that the subject of mildew on Rose trees is once more cropping up in your columns. I have long intended to give you my experience of the last season, but many things have conspired to prevent me. To be brief, I can say fairly that I have not had any mildew outside and very little in. I have not used a grain of flowers of sulphur, nor had occasion to. I am sorry to say that I cannot advance any reason for my immunity so far as outdoor plants are concerned, as I have treated them in my usual way. Of course I must admit that the summer was very dry, but so was that of 1884. Can the low night temperatures have had anything to do with it? Here we had frost every month in the year except January.

I found that by strict attention to ventilation I was able to "do without" mildew in my small unheated greenhouse. My constant aim was to keep the atmosphere as dry as possible. Some little time ago I could not agree with Mr. Bardney about the harmlessness of softsoap. I think now that the difference arose from the fact that Mr. Bardney grows his trees in

a heated house, and that after having syringed at night the foliage would be dry before the morning sun shone on it. In an unheated house the leaves would not be dry, and would thus be liable to injury from burning. I do not think that gypsum would do the Rose trees any good or any harm either so far as mildew is concerned. Some of the much-advertised fertilisers have a large quantity of it in their composition, so it can hardly be hurtful. I have tried nitrate of soda, but it did not seem to make any difference in the right direction; indeed, I think it made matters worse, as I have noticed that mildew is very partial to strong young growth such as would be produced by a stimulating manure like nitrate of soda. Of course I am glad to have escaped my enemy this one season; but will somebody please tell me why I have escaped?—T. C. CLAYTON.

### CANKER IN FRUIT TREES—THE COBHAM APPLE.

ALLOW me to express my thanks to all the correspondents who have given us their opinions on this subject. It was not my intention to trespass on your space or patience with any further remarks, as it is evident if I felt inclined to follow each writer, and comment upon his opinions, it would result in leaving the matter undecided. There are a few matters arising out of the discussion that I will refer to with your permission. A correspondent (I have not all the numbers of the Journal by me to refer to for names) asked where he could obtain trees of the Cobham or Pope's Apple. It is included in the catalogue lists of Messrs. Bunyard and Veitch, and possibly others. I believe if it was more generally known and grown that English Apple growers would be able to supply the home markets where Americans do at present. There is a reference to a paragraph of a tree of mine on page 132, February 14th, 1884. Last year it was equally overhurdled, and I now enclose one of the Apples as a fair specimen in comparison with Blenheim Orange as they grow with me.

Another correspondent, I think, asked what was my remedy for canker. This has been given on two former occasions on page 132, February 14th, 1884, and page 222, September 10th, 1885. I have found the following effectual on trees that are not too large to be overhauled. Cutting off all cankered wood where it can be spared, or cutting out the mound to a clear ring of bark on branches that cannot well be spared on account of spoiling the balance and disfiguring the trees, and then thoroughly dressing every hit of bark with Gishurst compound or other insecticide mixed into the consistency of paint with quicklime and applied with a painter's brush, or for expediency and support against weak wood I work a brush on each side of the hough at the same time. I repeat "thoroughly," for if any portion is left untouched the insects may escape to breed and spread, and as some of these mites, acari, or whatever they are, which I contend start canker, only occupy about a forty-thousandth part of an inch of surface, let it be understood.

I am much obliged to Mr. Harrison Weir for his correction on page 567. I wrote from memory, and as it is nearly two years since the article appeared, and I have not the number to refer to, I must allow him to know best. He further confirms my observations and experience.

I am also much obliged to "A Thinker" for the amount of thought he put into the subject on page 536. If he had gone no further back than page 222 he would have found that I have not "confined my observations to my own trees," by some thousands probably. It was this fact that made me feel so confident that, no matter from what part of the kingdom I obtained specimens, I believed I could trace the result to insects. If your correspondent will look back to page 132, February 14th, 1884, he will find that the Astwood Amateur Gardeners' Society discussed the subject at four or five meetings, members bringing their own specimens, which I placed under the microscope. It was the complaints of others that induced me to take up the subject, and not as some may suppose, that I am most unfortunate in being troubled with more than my share of canker. It has been a most interesting study, but it has occupied too much of my time. I am thoroughly acquainted with the "genuine" canker and the ulcerations; the latter is generally, if not always, caused by American blight. Why is it called the "American" blight? I never remember seeing it in America. Was it not known before America was discovered, I wonder, or how introduced?—J. HIAM, *Astwood Bank, Worcestershire*.

[The Cobham Apple sent by Mr. Hiam is a fine well-coloured example. It is the same variety as described by Dr. Hogg in the "Fruit Manual" as follows:—Fruit large; ovate, handsomely and regularly formed. Skin clear yellow, tinged with greenish patches, and strewed with dark dots; on the side next the sun it is marked with a few faint streaks of crimson. Eye large and open, like that of the Blenheim Pippin, and set in a wide and plaited basin. Stalk short, deeply inserted in a round cavity, which is lined with rough russet. Flesh yellowish, tender, crisp, sugary, and juicy, with a rich and excellent flavour. A very valuable Apple either for the dessert or culinary purposes; it is in use from November to March. This variety has all the properties of the Blenheim Pippin, and is much superior to it, keeps longer, and has the great advantage of being an early and abundant bearer. An excellent dessert Apple, with somewhat of the flavour of Ribston Pippin. September to January. Dr. Hogg met with this excellent Apple in the neighbourhood of Sittingbourne, in Kent, about the year 1842. The account he received of it was, that the original tree grew in the garden of a cottager of the name of Pope, at Cellar Hill, in the parish of Linstead, near Sittingbourne. It was highly prized by its owner, to whom the crop afforded a little income, and many were the unsuccessful applications of his neighbours for grafts of what became generally known as *Pope's Apple*. The proprietor of Pope's cottage built a row of other dwellings adjoining, in the gardens

of which there were no fruit trees, and, for the sake of uniformity he cut down Pope's Apple tree, notwithstanding the offer of 20s. a year more rent to spare it. The tree, being condemned, was cut down in 1846, at which period it was between fifty and sixty years old. The name of Cobham was given to it by Kirke, the nurseryman at Brompton by whom trees were distributed.]

### AN ORCHID SOCIETY.

THERE seems a desire on the part of a good many people that there should be steps taken to procure the formation of an Orchid Society, and for many reasons it seems desirable that such a society should be formed. It would of course be necessary that the society be supported and acknowledged by all, or at least the great majority, of the leading Orchid cultivators, importers, and all the leading nurserymen and recognised lights in the Orchid world. This will be the only way in which the society can be as useful as anyone desirous of starting it can wish.

Nomenclature should be submitted to the society, and by that means there might be some reduction in the endless multiplication of "variety" names, which at present are given so freely by one and all of the importers or cultivators of Orchids in our land. All varieties should be submitted to the society before being honoured with distinctive names, which in some cases at the present time are bestowed without enough to warrant them being given.

Then I should imagine that such a society as is proposed would endeavour to hold Orchid exhibitions in various parts of the country, and in order to do so a fund would need to be raised to enable prizes to be offered. Of course such awards to Orchids as are at present bestowed by the Floral Committee of the Royal Horticultural Society in the shape of medals and certificates would be awarded by the proposed Orchid Society. The goodwill and co-operation of the Royal Horticultural Society would of course be looked for, and doubtless will be accorded by the majority of its members.

It would be very necessary that, as far as possible, a National Orchid Society be formed, wherein Orchid cultivators of all degrees and from all quarters would find a welcome, and where no signs of trade or other jealousy would be allowed to crop up. Orchid cultivation is becoming very general, and in view of the ever-increasing importations, and the lowering in price of many fine Orchids, also the increased amount of knowledge being circulated regarding them—a knowledge that tends to make people aware that many Orchids are very easily and cheaply cultivated—it seems that a still more general culture of them will mark the future, therefore an Orchid Society is one of the horticultural events that seems probable at no distant date.

I have no doubt all who are really anxious to see real and permanent good result from the formation of such a society will come forward at the proper time with support of all necessary kinds, whether advice, pecuniary aid, or exhibits when the society has reached the length of holding meetings.—A CULTIVATOR.

### THE INSECT ENEMIES OF OUR GARDEN CROPS. THE APPLE.

OUR forefathers, excellent men in their time and way, cannot be credited with the merit of being accurate observers of Nature; no, supposing we were to go back but a century or two. Hence comparisons between the climate of our island now and in the past can never be made without some measure of doubt, yet we are tolerably safe in assuming that, if variable, it is on the whole more equable than once it was; the summers are not so hot, the winters are not so cold. I have been asked how the insect pests of our gardens have been affected by the change. I am inclined to think it has cut both ways, as we say. Evidence proves that mild and moist winters are unfavourable to insect life generally in gardens or out of them; the reasons need not be detailed. Thus far we are the gainers. On the other hand, warm long summers lead to a rapid multiplication of some species which at present are of comparatively little trouble to us. Now, with reference to the Apple, the yearly crop of which, even in these small islands, amounts to a considerable sum of money. I believe we should be right in saying that, apart from the admirable methods of dealing with insect enemies, of which formerly people knew nothing, it is a tree less infested than it used to be, especially by caterpillars. True, some species new to us have appeared on our Apples from time to time, but they have been kept under, and we have learnt a good deal through them. At all events, we have advanced beyond the careless modes of fruit growing once prevalent, when small heed was taken to obtain the full yield from an orchard, and some yearly loss, more or less, was taken for granted, but the margin of profit forbids such easy going now.

The large and usually conspicuous feeders on the Apple tree in one stage or other of its growth may take rank before the lesser fry as belonging to a nobler group of insects, yet in fact many of the small species are most to be dreaded because of their numbers and activity. I have had shown to me, with looks of apprehension that provoked the smile, the almost adult cater-

pillar of the eyed hawk moth (*Smerinthus ocellatus*), a creature which, being about 2 inches long, might be supposed to consume a large number of leaves; but it is not a ravenous eater compared with some big caterpillars, nor is it at all usual to discover this species abundantly in one spot. The eggs are distributed one by one generally on trees and shrubs. The preference of this species is given to Willow and Poplar, but it does occur on Apples, especially in low-lying orchards, feeding in July or August. The caterpillar, of a greenish white, seven-striped, and having a blue horn, is best removed early in the morning, when, probably to aid the digestive process, it reposes with head erect. Or it may be that this peculiar attitude is taken up to deceive the birds. In books detailing the Apple insects of the continent, mention is made of the Hawthorn butterfly, or black-veined white, as a species frequently observed infesting the Apple, and

Fig. 18.—*Bombyx neustria*. (See page 72.)

since the caterpillars live in colonies they might strip young trees if left alone. With us at present this butterfly breeds only upon the Hawthorn, and, thanks to collectors perhaps, it is scarcer in Britain than formerly. Then, again, there is the insect oddly called the gipsy (*Bombyx dispar*) very rare here, well known on the continent. By the Germans the shaggy large-headed caterpillar is styled Grosskopf. During autumn the females lay patches of eggs upon the Apple bark, from which companies of the larvæ appear in spring and infest the buds while they are expanding.

That destroyer of so many trees throughout Britain, the powerful-jawed long-lived caterpillar of the goat moth, may occur within the wood of Apple, but it has not been observed by me. A kindred, though smaller insect, the leopard (*Zeuzera asculi*) is a foe to our fruit trees, but seemingly likes the Pear better than the Apple. The late Edward Newman noticed that trees in which this caterpillar is boring will for a time bear better than usual with a sort of spasmodic energy, and may live many years, unless the tree is brought to the ground by the wind owing to the presence of the hollows in trunk or branches which open here and there to the outer air. I have repeatedly seen orifices in the bark of infested trees, besides those larger ones that the leopard leaves when it emerges as a moth. It is scarcely probable that the caterpillars migrate from tree to tree, and these holes of varied size may be designed to admit air. To us they are of advantage, since by judicious insertion of a flexible piece of wire the insects may be either drawn out or crushed, also by help of a syringe tobacco water, or a soapy solution, can be thrown up holes that lead to galleries beyond reach. Some advise a hunt for the eggs during the season the moth is out—that is, in July and August, but really this is of little use, for by her ovipositor the female thrusts them under strips of loose bark where they are hidden from view. At first they feed on the wood and the inner bark, but are soon strong enough to begin their mines, which are enlarged as the caterpillars grow, and it is believed that this life continues nearly two years. It is a species which would do much more mischief did not the showy spotted moth fall a frequent prey to birds and bats. Those moist places that appear upon trees that have been injured by this insect sometimes warm with mites; they, of course, are not the cause of any mischief, but a consequence of the harm previously done.

Popular authors who have written upon the gold-tailed and brown-tailed moths have given us some trouble by confusing the two species, and the Latin names also have been interchanged. No doubt the insects are much like each other in all stages, but it can be definitely asserted that it is the brown-tail (*Liparis chrysorrhæa*) which has been supposed to be hostile to fruit trees, the brother species seems to keep steadily to the Hawthorn. There is one important point of distinction—both hibernate, and the juvenile gold-tail when autumn gets chilly retires to a silken cell he spins, in which he leads a hermit's life until the spring. On the other hand, the caterpillars of the brown-tail, having kept together from infancy, form a common abode with several apartments, and there they abide through the cold weather, or the damp, as it may be. I have observed that a rainy winter kills many colonies. Herein lies an advantage to whoever may aim at the destruction of the species where it is injurious. Nothing is easier than to clear off these nests and burn them after the leaves have fallen. In France and Germany, however, there are two

broods yearly, and the insect does still haunt various fruit trees, the Apple among them, as it once did about Kent, and probably other English counties, but now it occurs here solely on Blackthorn and Whitethorn. For another reason it is a caterpillar unwelcome in gardens or orchards. At every moult a number of loose hairs are sent floating which cause irritation to the human skin.

The lackey moth (*Bombyx neustria*, fig. 13; see page 71) lays its eggs every year upon the Apple, though this is not its sole food, and the colonies of caterpillars are numerous some years, their webs being hidden often in the fork of a branch, whence they issue forth to feed; called lackeys, perhaps from their going forth in a sort of procession, but it has been also said that they may have been likened to the striped garb of livery servants—far-fetched this. It is a limp caterpillar, unmistakeable from its blue head with two black spots resembling eyes, and stripes or lines down the back, a central one of white, on each side of it others of orange, blue, and black. After the third moult, about the middle of summer, the caterpillars scatter. The best time for clearing away their nests is during May, if previous measures have not been taken against them while young, as by syringing the trees. Also the bead-like circles of eggs may be detected on the branches in winter.—ENTOMOLOGIST.

### HORTICULTURE IN 1885.

I HAVE for some years been accustomed to review at the commencement of each year the principal points in connection with our favourite pursuit which have struck me during the past year; and although the same course has been adopted by your correspondent who signs himself "A Thinker"—are not most of us thinkers?—yet I do not depart from my usual custom, as we do not travel on the same lines or discuss the same subjects. My task is much more commonplace, and in truth I have to deal more with a narration of facts than the discussion of questions which do not fall within my ken. I am but an "individual" who, in a humble way, tries to bring forward some facts which, ere the year grows much older, may as well be gathered up and not forgotten. I have written "individual," to which my friend Harrison Weir objects rightly. One is reminded of the story of O'Connell, whose vocabulary of abuse was very extensive, and who undertook that he would silence one of the Dublin "fish fags," who were as celebrated in this way as the Billingsgate fish wives. After they had been firing away at each other for some time, and the "Liberator" began to be in despair, he turned to his opponent and in thundering tones cried out, "You're nothing but an individual." This finished the battle. She succumbed, and left O'Connell victor.

It is an age of Congresses, and the past year has witnessed two very successful ones in connection with horticulture. Orchids and Pears have both been considered worthy of being so honoured, and there can be but little doubt of their usefulness and success. Orchids are, it is true, the aristocrats of Flora's kingdom, but their extended culture, consequent upon the better knowledge of their requirements, has given them an interest to thousands who never formerly dreamt of the possibility of growing them, are now keen in their culture. We have often wondered what is the state of those habitats from whence come the immense importations to which every year witnesses, and by many it has been thought that they must be denuded of plants; but I believe this is a fallacy. The richness of tropical vegetation, the ready manner in which seeds are produced and scattered, the rapidity of growth in tropical climes prevent this; and it is a curious fact, that although Orchids are wonderfully developed under cultivation, their flowering stems increased in number and the individual flowers in size, yet that they are difficult to seed, while in their natural condition they seed very freely. The stories that are told about collectors burning what they could not take away is one of those delightful inventions which amuse some and horrify others. The Orchid Congress has probably suggested the idea which is now put forward of an Orchid Society. We all know how special societies tend to encourage the growth of the flower they take in hand, as witness the National Rose and National Chrysanthemum Societies. Orchid growers, as a rule, would not care a great deal for large money prizes, but medals for excellence of cultivation rather than the introduction of new varieties would be greatly prized. It would not be difficult to work it out on the lines of the Societies named, but it should be regarded as a *sine quâ non* that it should be connected in its metropolitan doings with South Kensington. Whether it would do much as far as our provincial towns are concerned is questionable. The exhibition of Orchids at the Whitsuntide Show of the Manchester Botanical Society far exceeds anything we have in London, and it is a matter of doubt as to whether any extra encouragement would bring more Orchids forward. However, these are things connected

with the future, not the past, although the past has led me into this digression.

The Pear Congress did not excite so much interest as the Apple Congress of last year, probably because the commercial value of the latter is greater, and it is more everybody's fruit than the Pear; yet a good Pear is a highly prized fruit, and when we read that upwards of 740 varieties were exhibited, there is surely work for the experts to do in weeding out a vast quantity of worthless sorts and in fixing the synonyms of "too-much-alike" Pears.

The past year has produced, as every year does, many new plants, both introductions from other countries and hybrids raised in our own country. These have been in all departments of horticulture—in stove, greenhouse, and hardy plants. It is becoming every year more and more evident that there is an immense variety in the plants of the same species in their native habitat, almost as great as is to be found in the cultivated flowers of our gardens, and hence even amongst Orchids there are continually appearing novel and beautiful forms, thoroughly distinct from those we already possess. We get white *Odontoglossums*, as in *O. vexillarium* *Measureanum*; while the hybridiser gave us the same results, as in Mr. Seden's *Calanthe Sedeni candidibulum*. Yet, taking all things into account, I do not think that anything calling for extraordinary notice has made its appearance—nothing so sensational as *Anthurium Andreanum* or *Vanda Sanderiana*.

Florists' flowers (properly so called) have held their own, although it was a very trying year. The prolonged period of drought was a prolific cause of thrips and aphids in a great many plants; hence the Dahlia Show at the Crystal Palace showed a great falling off in quantity and, indeed, in quality also. I heard one very experienced grower say that he thought each bloom of Show Dahlias must have cost half a guinea to produce! the labour of watering, &c., had been so great. Of the Rose season I have already written, and have stated that it was not remarkable for the production of any very great novelties. Gladioli have been more largely shown, and many new varieties have been certificated. A good deal has been said about Lemoine's seedlings, but as yet they do not seem likely to elbow out the varieties of the *Gandavensis* breed. They are deficient in the length of spike, and there is at present no great brilliancy of colour. With me, too, they have the disadvantage of not blooming until very late, so that many of the blooms succumb to the frost; much in the same way as *Schizostylis coccinea* does. They are planted in the border in front of my greenhouse, are left there through the winter, and so can come up when they like. When I mentioned this to Mr. Gumbleton, who grows them largely, he was much surprised; but then Cork is much warmer than Kent, and not only will things flourish out there which we cannot attempt, but those that do flourish are much earlier. But of all florists' flowers, that which has during the last few years made the most rapid progress is the Chrysanthemum. In all parts of the country it has been fostered. Societies have sprung up and exhibitions held, while the National Society, formed on the same lines as the National Rose Society, has been greatly developed, and has done much to encourage their growth. This is not to be wondered at—it is everybody's flower. It comes at a season of the year when flowers are scarce, and now what with early and late-flowering varieties its season is prolonged for many months. In the Japanese section there has been a very large accession of new varieties—so large as to be bewildering—and I daresay, as in most florists' flowers, they will require considerable weeding out. Amongst the incurved varieties the novelties have been sports from other flowers and not seedling varieties; indeed, taking the prescribed model as a standard, it is hard to say where any improvement is possible, unless brighter colours could be introduced. Amongst reflexed flowers the palm must be given to *Cullingfordi*, very bright in colour and excellent in habit. In the Pompon sections there has not been much of novelty; indeed, this is most to be found in what are called Japanese Anemones; but whether the novelty is accompanied by beauty is, I think, very questionable.

Notwithstanding the depression which has been so universal, the interest in horticulture has been well kept up. Unfavourable seasons have been fatal to many societies, but others have taken their place. The increased number of horticultural publications evidences an increased interest in the pursuit, and also a wider area over which that interest is spread. These penny periodicals are marvels of excellence and cheapness, and those of us who can look over half a century of horticultural life may well expatiate upon the advantages which lovers of gardens now have. It can be from no lack either of teachers or teaching that mistakes are made in gardening, although I daresay it will be a matter of question when it is true that "in the multitude of counsellors there is wisdom," and when "too many cooks spoil

the broth." Amongst the means that have during the past year been adopted to advance the interests of horticulture have been the evening conversaziones of the Horticultural Club. We hope that there may be an increase of members consequent on this, for in many ways the Club is designed to meet the wants of horticulturists.

There is one point which in the review of the past is ever powerful—the reading of the death-roll, and the past year has taken away from us many whom we could ill spare. It is a testimony to the healthfulness of the calling that amongst them were Mr. Ellacombe, who died at 95; Mr. Chater at 84, and Mr. Drewitt at 85, and these gentlemen retained their faculties and their love of the garden up to the very end. Mr. Ellacombe was in his 94th year when I had the pleasure of visiting him at Clyst St. George, and a more wonderful and charming example of extreme old age I never saw. His memory was good, his love of his garden as great as ever, and his talk upon his favourite subject as instructive as any listener could wish. Amongst others who have passed away from us were some who were valued and personal friends. In Mr. George Baker of Reigate, the kindly and courteous Vice-President of the National Rose Society and the most enthusiastic of Rose lovers, many, very many, miss a valued friend. Then that king of florists, Charles Turner, has also gone from us. Associated as he has been with my life-long pursuit of florists' flowers, one has had the opportunity of comparing him with others who have travelled on the same lines, and one has no hesitation in saying that he was a head and shoulders above his fellows, and that he has done more to advance their cultivation than all other florists put together. Of him it was true in a floricultural sense there was nothing that he touched that he did not adorn. Every flower he took in hand he improved and increased its popularity. There was not one of them in which his name is not associated with new and improved varieties. No man had greater perceptive powers, and at a glance he could take in the merits or demerits of an exhibit, and, what is rarer still, could see where his own were faulty, which, to tell the truth, they very seldom were. Amongst all those who passed away last year there is no one I have personally more missed or who was a greater favourite amongst his fellows than James Cutbush. He had long presided over the Highgate firm, and had successfully carried out the culture of bulbs, especially the Hyacinth. It was ever a pleasure to meet him. He battled cheerfully against continued ill health, and was ever cheerful and pleasant. It is a great matter to know that in the case of these two firms sons trained in their father's ways still keep the old name up, and that neither Charles Turner nor James Cutbush disappear from our lists of floriculturists. Mr. Chater was long known as a successful rearer and cultivator of the Hollyhock, while Mr. Drewitt long presided over the lovely gardens of Denbies. And so our ranks become thinned, new faces meet us, new acquaintances are made, but will they ever replace the friendships of bygone days? I think not.

And so must end my brief review of the past year, chequered as it must be with its sunshine and clouds. Let us hope that its teachings may not have been lost on all thoughtful readers of the Journal. They need not be if we are wise in our day and generation.—D., Deal.

#### FAIRLAWN HOUSE, CHISWICK.

It has doubtless been the experience of some who have visited large gardens that their very extent has been a source of disappointment. So much is spread before the eye, there are so many surprises, that a sense of bewilderment is sometimes the result. This thought has been suggested by a recent inspection of a small garden, one that lays no claim to pretension, and yet that has a quiet charm. It is situated near to the Acton Green station of the District Railway Company, and stands close to a spot that has an interest for those who are of an historical turn of mind, for near here took place a sanguinary conflict between the Royalists and Cromwellians. The garden contains a good and tastefully arranged collection of Chrysanthemums; some 350 plants being grown then (December), making the little conservatory gay, had an especial charm for lovers of this truly popular autumn favourite; and the display would not have disgraced larger gardens.

The majority of blooms are taken by the gardener, Mr. Davis, from the crown bud, these producing the earliest and finest blooms, those on the terminal coming in for later wood. He is a believer in what is called the cutting-down process, and means to adopt the practice more extensively in the future, plants thus treated producing the greatest quantity of flowers, not perhaps coming up to the exhibition standard, but still valuable for decorative purposes, a point for consideration in private establishments.

I noted a few varieties that were doing well—necessarily space forbids our giving any long lists—and append their names for the benefit of those who wish to grow a collection in a small garden. Those who disregard formality, and do not want to see flowers as though turned out of a mould, find the Japanese the best. In this class we noticed as

especially good Lady Selborne, that snowy-white grand flower, sport from James Salter; Mdle. Lacroix, long drooping sulphur white florets, very graceful and handsome; Madame C. Audiguier, colour deep mauve beautiful, of great size, a magnificent flower; Mdle. Moulise, a large sulphur white flower, with long twisted petals, a fine exhibition flower; Thunberg, pale yellow, twisted florets, very attractive and fine.

Amongst the incurved that old but still most exquisite flower, Princess of Wales, was very attractive with its fine blush-tinted rose flowers; Mr. Bunn, an improvement on the well-known Golden Beverley; Beverley, a fine pure white flower; the sport from Mrs. George Rundle, George Glenn, is a beautiful flower, colour a pale yellow or primrose; Mrs. George Rundle, a fine white; Venus, a very fine peach-coloured flower.

In a house adjacent to that in which were the Chrysanthemums we noted some well-coloured specimen Crotons, Queen Victoria being specially noticeable, that lighted up the house. A few specimens of *Cycas circinalis* were also noteworthy, it made fronds from 6 to 7 feet in length last year, and is very telling as a group plant. It was purchased when the Orleans House fine collection of plants was disposed of. Those effective Tree Ferns, *Cyathea dealbata* and *C. princeps*, deservedly merit notice. Fuchsias, pyramidally trained, are a speciality, and often put in a successful appearance at the local shows. Fuchsias as a rule are not well done at London shows. As might be expected in a place of this description, fruit-growing is not carried on to any extent. A vinery is devoted to that everybody's Grape, Black Hamburgh. A crop of some 200 good medium-sized bunches was produced last season, and the Vines are in capital condition for future requirements. Apples and Pears are grown just to suit only a moderate demand for them, a tree of that valuable late culinary Apple, Damelow's Seedling (Wellington) has borne about 13 bushels of its valued fruit. An unpruned pyramid Pear, Calebasse, some 20 feet high, having yielded 8 or 9 bushels of its large fruits.—B.

#### NOTES FROM A NOTTINGHAMSHIRE GARDEN.

WILL "A. M. B." care for a few suggestions for her herbaceous border from a neighbouring county? as the climate of north Notts and mid-Lincoln must be much the same. At all events we have been enjoying much the same variations of temperature lately as those "A. M. B." describes. Earliest of all here (except the Christmas Roses) are the Cyclamens Coum and Atkinsii. C. Coum had several bright crimson blossoms on the 16th, having already weathered one spell of frost since it began to flower. Since that date (I am writing on the 24th January) it has been covered with snow, from which I hope it will emerge as brightly as before when the thaw comes at last. I am sorry to say that I do not find the later-blowing hardy Cyclamens as satisfactory as the winter ones. C. vernalis gives us a few of its pretty rosy flowers so much larger than C. Coum, but it seems to feel the spring frosts, and the clump dwindles and does not increase as C. Coum does. Cyclamen europæum has so far not grown at all with me; and what I believe to be C. hederæfolium, which I brought from Algiers four years ago, though it throws up its large handsome marbled leaves each autumn, does not flower. Indeed, my Algerian plants have not been very successful. Anemone palmata comes up every spring, but does not bloom (I have planted one clump of it in peat, where I hope it may succeed better), and Iris stylosa, which I keep in a pot in a cold frame, has only bloomed once, and then in the October of 1884, hardly the right time of year.

Then in the spring Primula rosea, with its bright pink heads, is very charming. If the sparrows will only abstain from picking off the blossoms it increases very rapidly. From two tiny plants purchased in 1879 I have now a large enough stock to use it freely as a bedding plant for the spring beds, besides having clumps about the garden, where it certainly prefers the moist corners. We also find Triteleia uniflora very useful for bedding. It does not seem to mind being moved twice a year. Primulas cashmeriana and denticulata with their lilac heads form a pleasant contrast to the Doronicums, Adonis vernalis, and hosts of yellow Daffodils which bloom at the same time.

As to Daffodils and Narcissus, the difficulty nowadays is to choose between them, and though we have over thirty varieties that is but a small collection. Perhaps pallidus præcox, Horsfieldi, moschatus, Stella, Orange Phoenix, and the double and single Poeticus are among the most distinct; but then we cannot do without the delightful Hoop Petticoat and the Queen Anne Jonquil.

What beautiful colours there are among the species of Tulips, the brilliant orange scarlet Greigii and the yellow Florentine growing in bunches, and bright Monstre Rouge Parrot Tulip, though of the latter we sometimes complain that the flowers open green and do not colour in a cold spring. Then Phlox setacea and its varieties make pretty pink carpets for the front row of a border; and Trillium grandiflorum with its beautiful white flowers will do for the shady places, and Megasea with its big leaves and pink flowers seems to thrive and increase everywhere. Then there are Crown Imperials and purple and white Rockets and Flag Iris. The Iris seem nearly as vast a

subject as the *Narcissi*. The beautiful tall *Iris ochroleuca* perhaps prefers a damp situation, but it does well on an ordinary border, and there are many coloured English and Spanish *Iris*. The *Pyrethrums*, double and single, great Oriental *Poppies*, *Papaver umbrosum* with its crimson flowers and black blotch, and hosts of French and Opium *Poppies* which seed themselves only too freely. *Delphiniums*, among which *Belladonna* and *Cantab* are the prettiest of the pale blue kinds. Mrs. Sinkins Pink is very useful for cutting from, and so is *Campanula coronata alba*, figured in this week's Journal, and the dwarf *Campanulas pusilla* and *pusilla alba* are charming for the front line, and so are the dwarf *Oenotheras*, the white *taraxacifolia*, and the yellow *macrocarpa*.

*Scabiosa caucasica* is such a pretty soft grey, an unusual colour among flowers. We did not think much of it when it was growing in poor soil, but since the bed has been trenched, fresh soil dug in and replanted, it has rewarded us with a profusion of bloom all the summer. The dwarf *Aster alpinus* is very pretty, and the curious *Eryngium amethystinum* is well worth growing. *Gaillardia grandiflora* is very handsome. The winters have been mild since we have had it, so that we have not been able to ascertain if it will resist a hard frost. We always protect it with cocoa-nut fibre.

Besides *Lilium candidum* would not Orange Lilies—the scarlet *chalconicum*, and the buff *excelsum* or *testaceum*—thrive in the mixed border; and the Tiger Lilies, *tigrinum splendens* both single and double? *Lilium umbellatum* is strong-growing, and a richer colour than the Orange Lily, *Lilium croceum*. We grow plenty of *auratum* and *speciosum*, but the former requires peat, and the latter is rather delicate for the mixed border. Then in September the lower-growing *Michaelmas Daisies*, such as *Aster amellus* and *bessarabicus*, make a pleasing group with *Rudbeckia Newmanni*. *Sedum spectabile*, too, with its bright pink heads is very useful at that time.

For fine-foliage plants there are *Funkias* and *Bocconia cordata*, but the latter requires watching as it spreads so rapidly that it smothers all its neighbours. The soil here is very sandy and dry. We have abundance of water, having a pond and several streams, and as the garden lies low we suffer very much from frost, and lost far more evergreens, &c., than our neighbours in the cold winters of 1879 and 1881. We also suffer very much from weeds. I do not know the Sweet Ash alluded to by "A. M. B.," at least under that name; but I almost despair of succeeding in eradicating ground Elder, Rampion, and Bindweed from the wilder parts of the garden, while Dog's Mercury is rapidly smothering Primroses and Periwinkle in the adjoining wood.—A. M., *North Notts*.

## PROPAGATING WINTER-FLOWERING CARNATIONS

TREE Carnations are deservedly popular, and to become a successful cultivator of them a beginning must be made early in the year—that is, if it is desired to have good-sized plants capable of producing a profusion of flowers. By the 1st of January of the present year I had some cuttings of *La Belle* and *A. Alegatière* well rooted. These I had secured from some old plants which was not intended for flowering, some old, almost worthless plants in fact, but which in the end produced serviceable cuttings that, if well tended, will make fine plants by midsummer fit for 7-inch pots. Having grown and propagated this section of Carnations with fair success for some years I will detail the system adopted.

Propagation should always be commenced as early as possible in January, since cuttings taken at that time will be comparatively firm and hard, and will root readily in the propagating house, requiring neither bellglasses or frames to keep them close, and if no air be admitted at this season. Throughout January and onward till the middle of February, they are benefited by slight bottom heat—say 60°—and partially plunged, but on no account cover them with glasses or lights. Let them remain open, otherwise they are likely to suffer from damp. For later batches of cuttings I prefer striking them without bottom heat, and for this reason: that with the advancing season the house will be kept somewhat warmed, the cuttings will be of quicker growth and consequently more sappy, which, coupled with the bottom heat, would soon place them beyond recovery. So long as I can procure hard woody cuttings I prefer gentle bottom heat, the cuttings being uncovered; but when obliged to resort to soft cuttings, then I prefer cool treatment, and employ bellglasses, and let it be remembered that the Carnation is a greenhouse plant, in fact nearly hardy, and consequently it is at no time benefited by too much heat. I have never found any cutting too hard or woody to root, but generally the woody cuttings root most freely and quickly. This is not so widely known as it ought to be, or we should see more Carnation flowers during the dull months of the year. Not infrequently do the inexperienced deliberately cut off that portion of the cutting—i.e., the heel—which is the readiest to emit roots. In all cases, then, where possible, strip the cutting off with a heel attached, for though a cutting severed at a joint will root, the chances are greatly in favour of the former method. Let the cuttings be from 3 to 4 inches long, though it will not be possible to get them of this length from all the varieties, owing to the difference of habit and growth, some being very erect growers, as *A. Alegatière*, and others, as *Miss Jolliffe*, of dwarf bushy habit. Still, whatever may be the style of growth, it is always policy to wait for fair-sized cuttings before making a start.

For propagating purposes the soil I use is sandy loam, with about half an inch of coarse dry silver sand on the surface, and, having inserted the cuttings I give sufficient water to penetrate the whole of the soil, and allow them to remain till the following day before the glasses are placed over them; they will be dry by this time—an important matter, for damp may be said to be one of their greatest enemies in this stage. The glasses should be removed daily and wiped; beyond this they will need little attention. They will not often require water. Thus treated they will root in about a month or five weeks, depending to some extent on the weather, and when ready may be placed into 2½-inch pots, using fairly rich loam, making it rather sandy. If leaf soil is obtainable use it in proportion of one-sixth to that of the soil, taking care that the loam is free from wireworms. The only safe remedy I know is to catch and kill them, and this seems the one recommended by the older florists, as the following quotation from "Hogg on the Culture of the Carnation" and *Auricula*, &c., will show. Speaking of the wireworm among other pests the author says, "I met with two a few days ago, and tried what effect a little quicklime had upon them. I scattered a little over them, but it seemed to make no other impression than to induce them to move from it with more speed than they are accustomed to do. I brought them back to it again, and kept them there for a couple of minutes, but they were still able to crawl from it, apparently not much hurt by it. The only sure way to deal with them is catch and kill them." Its existence, too, is all the more to be dreaded, seeing that it works beneath the surface and is rarely detected save by the plant syringe.

When the plants have become well established in the small pots they should be stopped—that is, if they have attained a height of 3 or 4 inches, so as to make them bushy, or at least produce two or three breaks from the base of the plants; those that require a second stop will speak for themselves. By the end of May they will be ready for 5-inch pots, and should be in frames out of doors, where they may receive abundance of air, and as the season advances they should be staked; and, finally, about July be shifted into pots 6 inches or 7 inches in diameter according to the size of the plant. Use rich fibrous loam chopped fine and not sifted, with about one-third its quantity of well-decayed manure and leaf soil, with sufficient sand added to keep it open. A 5-inch potful of Clay's fertiliser to each barrowful of the compost may also be added.

Some of the best varieties are—*Vulcan*, *A. Alegatière*, *Lucifer*, *Prince of Wales*, all scarlets; while among whites we have *La Belle*, *White Swan*, *The Bride* (Hodges), the last a very fine flower. *Miss Jolliffe* is a pleasing flesh colour, *Mrs. Hawtre*y and *Pride of Penshurst* are good yellows, so also is *Andalusia* when well grown, though I have never been so fortunate with it as *Mrs. Hawtre*y, and my experience of it is that it is not so free-flowering.—J. H. E.

## AGATHÆA CÆLESTIS.

No garden should be without a few representatives of this truly charming winter-flowering plant. It is one of the easiest plants to cultivate, as with only ordinary care it will bloom profusely all through the winter months, while with a little extra attention it may be had with luxuriant dark green foliage and an abundance of its Daisy-like flowers all the year round. The flowers, as the specific name implies, are of a beautiful sky-blue tint with yellow centre, and by way of variety they are very useful for decorative purposes in a cut state. They are produced singly upon the branches of the plant, and are borne on erect and slender stalks. The plant prefers a rich loamy soil such as suits ordinary *Pelargoniums*, and when showing flower it will receive great benefit from occasional supplies of liquid manure. Plants required for winter-flowering should be struck early in spring, and then be potted and grown in a mild heat and gradually hardened off by the end of May. They should then receive a final shift into 6-inch pots, and after they have become established they can be plunged outside in a position well exposed to the sun. The effect of this plunging outside in a sunny position will be to produce bushy plants with thoroughly ripened growth, a state of things which it will be very difficult to obtain if the plants are grown in a house or frame; and besides, if the plants are plunged outside they will not require nearly so much attention as regards watering as they would do if they were otherwise grown, nor will they be so liable to the attacks of insects.

When plunged, care must be taken that they are not allowed to root through the pots, as they might thereby receive a severe check when the inclemency of the weather demands their removal indoors. On the approach of frost in autumn the plants may be taken in, and, if possible, placed in a cool house or pit where the atmosphere is dry and airy, but where a little heat could be turned on if damp or dull weather prevailed. All dead flowers and foliage should then be removed, and with a watering of liquid manure about once a week they will yield flowers in abundance. The only pests which are found to trouble the plants to any dangerous extent are the green and black flies, and these can easily be removed by syringing with diluted tobacco water when the plants are outside, or by fumigation when they are under cover. This plant is sometimes called the *Blue Marguerite*, on account of the great resemblance its flowers bear to those of the popular Parisian Daisy. The plants are members of the same natural order, and the flowers of both are very similar in form, but in all other respects they are distinct. It is a native of the Cape of Good Hope, and was introduced into this country about the year 1759.—PRUNUS.

## COLLINSIA MULTICOLOR.

EVERY gardener knows how difficult it is to keep up a gay appearance during the sort of interregnum which succeeds the flowering of the spring

bulbs, and before the majority of the herbaceous perennials and bedding plants are in bloom. For filling this void the autumn-sown Californian annuals are unrivalled; and, indeed, a succession of sowings would produce throughout the season an effect but little inferior to that obtained by the employment of any other plants.

One of these is *Collinsia multicolor*. It is quite as robust in its habit as the well-known *C. bicolor*, growing from 12 to 18 inches or more high; and its flowers are among the largest and handsomest of the genus, though their colour is less intense than in one or two older species. The foliage is larger and more coarsely toothed than in *C. bicolor*; but it is chiefly by the purplish tint of its floral leaves or bracts, which add much to the beauty of the plant, that it is distinguished from most, if not all, other species. The bracts beneath the lowest whorl of blossoms are cordate, bluntly toothed, and pointed; the middle ones are much narrower, and without teeth; the upper ones quite abortive. The flowers are on rather long pedicels, which, as well as the calyx, are almost free from glands. The segments of the calyx are very narrow, shorter than the corolla, and three-ribbed. The lower lip of the corolla is lilac, but the

Fig. 14.—*Collinsia multicolor*.

pouch-like cavity of the middle lobe is crimson, though externally this tint is hardly visible. The upper lip of the flower is also lilac, but with a large quadrangular white spot in the centre, speckled with bright rosy purple. We retain the name under which this plant was first published, but it is only right to observe that it is now regarded as but a form of *C. bicolor*.

The cultivation of *Collinsia multicolor* is of the easiest description. It is only necessary to sow the seed thinly, in patches, in the open border where the plants are to bloom; and this may be done any time between the beginning of March and the end of April. As the seeds are comparatively small they must not be too thickly covered with earth, especially if of a heavy adhesive nature. In soils of this character it is a good plan to cover the seed with a little pulverised sandy loam.

Besides *C. bicolor* already referred to, there are several very pretty species well deserving cultivation, the most important being *C. verna*, *C. grandiflora* and its recently introduced variety *violacea*, *C. heterophylla*, *C. corymbosa*, *C. bartsiaefolia* and its variety *alba*, and *C. tinctoria*.

*C. verna* is a very attractive early-flowering species, with the lower lip of the corolla of a sky blue, the upper lip being white. It would doubtless be more extensively grown but for the short-lived vitality of the seeds, which renders it necessary they should be sown in autumn soon after being gathered. From this defect *C. grandiflora* and its charming variety *violacea* are free, though the strongest plants are to be obtained by autumnal sowing, as well as the earliest blooms. The variety *violacea* especially deserves recommendation, the colour of the lower lip being much deeper than in *verna*, and the resulting contrast with the white upper lip more effective. *C. heterophylla* resembles *C. bicolor*, but its flowers are of a darker and perhaps less pleasing tint. *C. corymbosa* is very distinct as a species, with flowers in a capitate cluster and having an abbreviated upper lip, but is less showy and effective than those already named. Nor is *C. bartsiaefolia* worthy of more than a passing notice, its colours being somewhat dull; but its white variety is deserving of more attention than it receives, its colour being pure, and its habit so dwarf

that it would be found useful as an edging to taller annuals, though it is, like the rest of the species, comparatively short-lived. *C. tinctoria*, so named from the numerous glandular hairs which clothe the calyx communicating a yellow stain to the fingers when touched, is not yet, we believe, in cultivation.—W. T.

#### NOTES AT MAIDENHEAD.

WHEN recently visiting Mr. R. Owen's nursery at Maidenhead I was much pleased with the white reflexed *Chrysanthemum Boule de Neige*. Mr. Owen had quantities of very useful flowers yet to cut of this, and he considers it the best late white variety yet introduced. Other varieties are still flowering, amongst which may be noticed *Ethel*, *Fair Maid of Guernsey*, besides many seedlings of promise. In another house I noticed a variety called *Cloth of Gold*, seemingly a cross between *C. frutescens* and *C. carinatum*. It is by far the brightest of this section and flowers freely. Ivy-leaved *Pelargoniums* receive much attention, the most noticeable being a very promising salmon-flowered variety with white marking; *floribunda*; *Souvenir de Charles Turner*, a variety of great excellence which will become popular; and a seedling double with flowers  $2\frac{1}{2}$  inches across, one of the brightest yet raised. In another house seedling *Show Pelargoniums* are very vigorous, and something good is expected from them. *Zonals* also are grown in great numbers, with *Primulas* of a choice strain; the colours are numerous, some very rich; also excellent whites of the *Magnifica* strain. One very noticeable was a deep yellow-centred variety with white edging, somewhat like a *Primrose*.

There was a number of useful plants of the old *Eupatorium odoratum* in 6-inch pots admirably adapted for any purpose. A distinct fimbriated strain of *Cyclamens* is likely to become very useful when a little more improved. *Abutilons* are cultivated in large numbers, both seedlings and named varieties of the former; one was flowering of a very deep rich velvety crimson tint apparently of good habit. In a lean-to house were some healthy *Roses* in pots, and others planted out trained to the back wall seemed quite at home. A large collection of *Begonias* has received Mr. Owen's attention for some years past, and many fine seedlings are included.—J. P.

#### LYCASTE LANIPES AT OAKHOLME, SHEFFIELD.

THIS *Lycaste*, which appears to be not very generally grown in collections of Orchids, is now in especially good condition in the beautiful collection belonging to T. Wilson, Esq., Oakholme. It is a favourite with Mr. Hannah, the able gardener, as well as with his employer, and he has for several years past flowered it very finely. At the present time, however, it is better than ever before. He has two varieties, the flowers of one being much purer white, larger, and more waxy-looking than is the other. On this variety we counted thirteen flowers from one growth, each flower being about 5 inches across. The flowers are thrown up from the base of the pseudo-bulb on footstalks about 6 inches in length, and form a dense mass of inflorescence a foot or more across and of a very striking character. On a plant of the inferior variety there are twenty-three flowers produced from two growths. The foliage is very fine, being about 2 feet in length, very dark green, stout and massive, the pseudo-bulbs being from 5 to 6 inches in depth.

Mr. Hannah grows this plant in the East India house with *Phalænopsis*, *Vandas*, &c., the year round excepting during the time it is in flower. He gives it a very liberal supply of water during the growing season; and in the autumn, after growth is completed, he gradually diminishes the supply, thus inducing rest without taking the plant into a cooler temperature. He gives it as his opinion that this plant, in common with many varieties of Orchids, dislikes any disturbance at its roots. His plants have not been repotted during the last five years, and have each year increased in strength and in the number of flowers produced.

In the flower house at Oakholme there are now several Orchids in flower, and the general effect is very beautiful. Numerous plants of *Calanthe Veitchii* with exceptionally large and strong flower spikes form a fine background interspersed with a number of well grown *Poinsettias*. There are also *Dendrobium Ainsworthii* (a plant of this in a 7-inch pot carrying sixty flowers on three flowering growths); *Dendrobium nobile*, *heterocarpum*, and *D. phillipinense* (a plant of this Orchid has not been out of flower for five months); *Odontoglossum crispum*, six varieties; *Odontoglossum blandum*, very fine plants; *O. cordatum*, *Oncidium varicosum*, *Lycaste Skinneri*, *Laelias autumnalis* and *anceps*, large and strong plants; *Cymbidium Hookerianum*, and *Sophranitis grandiflora*. The latter are annually very fine, and have an especial aversion to frequent repottings.

In the East India house is a very fine collection of *Phalænopsis*, many of them very large specimens, and all of them in the most robust health and vigour. Seldom are they seen so fine. The main points observed in their culture here are at all times a liberal amount of heat combined with a moist atmosphere and freedom from draughts. In this house a fine plant of the singular and very attractive *Angraecum sesquipedale* is carrying five of its large flowers on two flower spikes; the spur or tail to each flower is about 12 inches long. The plant has fourteen leaves, and is apparently without a blemish. *Phalænopsis Sanderiana* is flowering freely, and is similar in general character to *P. amabilis*, but the flowers are slightly smaller, and have a very pretty shading of light pink appearing as if laid on the white ground colour. The small *Odontoglossum* house has a perfect forest of flower spikes in different stages of development. On a small table having an area of 12 feet by 5 feet we counted over seventy strong spikes. One plant on another table we noticed had seven spikes averaging fourteen flowers to each. Nowhere do we see *Odontoglossums* growing more strongly than at Oakholme.

The large plant stove is always a fine feature here, the collection of specimen Crotons being alone worth a long journey to see. The plants are very large, 6 or 7 feet high, and almost as much through, very clean, and wonderfully bright in colour. Amongst a many good things in this house especially noticeable are fine specimens of *Sphaerogyne latifolia*, with twelve full-grown leaves, very massive, and without spot or blemish; *Heliconia aurea striatum*, fine plants, very brightly coloured; *Anthurium Schertzerianum*, a massive plant of a grand variety, throwing up about a hundred flowers; *Adiantum farleyense*, two fine specimens, each about 5 feet over. In another house we noticed *Eucharis amazonica*, candida, and *Sanderiana*, all flowering side by side, the two latter serving as foils for showing up the superior beauty and excellence of the first named old favourite. We also noticed a collection of seedling Crotons raised there, one or two of which are, we believe, destined to become popular varieties, especially so a cross between *C. Weismanni* and *C. Veitchii*.

In the conservatory is a fine collection of late Chrysanthemums, which for some years past has been made a speciality. The varieties principally grown are Princess of Teck, Hero of Stoke Newington, Guernsey Nugget, Jardin des Plantes, Mrs. Howe, Dr. Masters, and Fleur de Marie. Of the two first named numerous large bushes are now—January 7th—freely opening fine flowers in abundance, and bid fair to be very fresh and good for several weeks yet to come. A number of large plants of the Gladiolus-like *Schizostylis coccinea* are very effective. The numerous flower spikes are each about 2 feet long, and the individual flowers 3 inches in diameter. This plant is one of Mr. Hannah's especial favourites, and no one, I believe, succeeds better in its cultivation.—W. K. W.

#### HARDY FRUIT GARDEN.

**BUSH FRUIT.**—Faulty practice in the culture of bush fruit is by no means uncommon, and an instance of it which came recently under our notice was a reminder that a good lesson cannot be too often repeated. Let us once more briefly enumerate the chief points to which it is important that close attention should be given. Gooseberries and Red and White Currants should be planted at least 5 feet apart in the smallest garden, and 6 feet whenever space can be had. Bushes crowded together at 3 or even 4 feet apart either grow into a thicket or are pruned so severely that very little fruit can be had; but 6 feet from bush to bush affords space for full development and for getting among the bushes for all cultural purposes. A few well-grown full-sized bushes will afford more and better fruit than twice the number of small bushes crippled and stunted by excessive pruning. Rich loam or its equivalent in well-manured and carefully prepared soil, is necessary. We have planted in soil with no more preparation than the digging in an ordinary dressing of manure as for a bed of Cabbages with perfect results, and we have had to drain, trench, mix lime, coal ashes, and a double quantity of manure where the soil has been poor, thin, deficient in lime and in stones or gritty matters to ensure success; and let it be understood that one can render success a certainty in any soil. It is, however, highly important that the soil is in such a sound, fertile, porous condition before the planting, because it must not be disturbed afterwards; there must be no digging among the bushes, only an annual dressing upon the surface of manure from the stable, cowyard, or piggery, any necessary hoeing of weeds in summer, and a liberal use of liquid manure during the season of growth. In pruning we remove all growth too near the soil, open out the middle of the bush, spur in side growth upon old branches, and leave new growth sufficiently thinned to let light and air have free play among it. At this season of the year the branches of Gooseberry bushes should be syringed with a wash consisting of soft soap dissolved in hot water and mixed with finely powdered lime and soot. This forms an efficient protection against the ravages of bullfinches. See that the syringing is so done that the branches and buds are quite covered with the wash.

**BLACK CURRANTS.**—The answer best in a deep rich loam, failing which trenches may be filled with rich manure mixed with soil. Plant 6 feet apart, see that bushes have no stems, our object being to develop strong stools from which stout shoots spring annually to replace old growth as it becomes exhausted and feeble. It is hardly possible to enrich soil too much for this profitable fruit, and the bushes must have a plentiful annual surface dressing of manure, and the soil a weekly soaking of sewage or other liquid manure in spring and summer. To be fully successful it is imperative that the soil be well stored with nutriment. If this is not done the bushes deteriorate quickly even in a deep loam. Do not spur Black Currants, but thin out the growths, removing all old and exhausted branches.

**RASPBERRIES.**—The soil for Raspberries requires very similar treatment to that enumerated for Black Currants. It was owing to a failure of a large bed of Raspberries planted by us in poor thin soil that we were induced to prepare trenches of very rich soil, made so by the free use of well-decayed stable manure, and we not only had stout canes 12 feet high, but those canes, headed down to about 4 feet, put forth side shoots

next season that were laden with a crop of fruit that was absolutely marvellous. At the planting the canes were shortened to 18 inches, with such excellent results that we have ever since adhered to the plan. In this note we have striven to show how extra pains in the culture of bush fruit is well rewarded by extraordinary results far superior to anything seen under ordinary practice.

#### FRUIT FORCING.

**FIGS.—Earliest Trees in Pots.**—With bright nights, and the temperature several degrees below freezing point, it is useless to think of increasing the night temperature. Advantage should be taken of sunshine to close early in the afternoon, or from one to two o'clock, with a rising temperature, and if blinds or mats can be drawn over the roof lights at night it will do away with the necessity for sharp firing without running the risk of giving a check that might prove fatal to the crop. The fermenting materials that have been placed about the pots should receive frequent additions of warm Oak leaves on the surface, working them in when turning is considered necessary for maintaining the bottom heat at 75° to 80°. It will be necessary to examine the pots frequently, particularly where they are partially exposed to the parching influence of fire heat, and give a good supply of tepid liquid. If properly drained and placed upon dry brick pedestals there is little danger of giving a pot Fig that is well furnished with foliage and fruit too much water. When fresh fermenting materials are introduced it will be the safest plan to have a little ventilation constantly at the top of the house. Syringe the trees in the morning and early in the afternoon, as red spider may be expected to appear after so much sharp firing. Stop all gross shoots at the sixth leaf, thin outside shoots and useless spray, that the young spurs and fruit may have the benefit of air and light. The thinning of the fruit should also have attention as soon as the most promising and best placed can be decided upon for the crop. Trees that have been some time under judicious treatment show more fruits than they can bring to maturity, hence the necessity of thinning, especially before the fruit takes the last swelling, at which state the Fig sometimes casts its finest fruit, and those left, owing to the check the trees receive, lack the flavour that gives them their value in our finest desserts.

**Succession Houses.**—Encourage a steady progressive growth by giving gentle fire heat and moisture through the day. Keep the borders well mulched, and give plentiful supplies of tepid water to the roots, but carefully avoid a high night temperature until the weather becomes more genial.

**Planting Fresh Trees.**—The present is a suitable time for making the needful preparations, and the trees should be placed into position as soon as possible. A limited space only should be accorded the roots, and even then borders may be made piecemeal. The bottom must be concreted, and have drains with proper outlet. A foot of good clean drainage, and over this place a third layer of turf, grass side downwards to prevent the finer particles of the compost from washing downwards. The compost may consist of turfy loam, rather strong but not very heavy, four parts; old brick and mortar rubbish one part, charred refuse and road scrapings in equal proportions one part, the whole thoroughly incorporated. Two feet depth of compost is sufficient, and when the border is raised to within 6 inches of the intended level, the trees, if in pots, will require shaking out, in order that the roots may be spread over the surface of the new bed, which should be made firm and even. Place 2 or 3 inches of soil over the roots and then water moderately to settle it about them, place on the remainder of the soil and defer mulching for the present. No variety surpasses Brown Turkey for general quality.

**Young Pot Trees.**—Trees that were struck from eyes last season should now be encouraged with warmth and moisture, as future success depends upon getting an early and thoroughly ripened growth. Remove all ground suckers, stop the strongest shoots, and train the leaders to straight stakes. Insert cuttings or eyes of favourite varieties, and plunge in bottom heat. Plants raised from single buds always make the best pyramids, growing on clean straight stems.

**PINES.**—In the fruiting compartments and others which contain plants about entering on that state the heating apparatus must be kept going, and as a consequence a certain amount of dryness will result unless sprinkling or syringing be vigorously enforced, but avoid sprinkling the pipes, taking advantage when they are least heated to well moisten the surroundings. Plants in light and lofty structures will need syringing much more frequently than those in low and damp ones. The necessity for syringing may be ascertained by examining the base of the leaves; if the axils contain moisture none need be given that way until that existing is nearly exhausted. Avoid wetting the fruit during the flowering process, as discoloration of the fruit at the base of the flower proceeds from this cause. The Queen and other varieties for the summer supply will have the fruits emerging from the sockets of the plants. Every encouragement should be given to these to enable them to throw the fruit well above the foliage, attending to watering, bottom heat, &c., and affording a night temperature of 65° to 70°, and 75° in the daytime.

#### PLANT HOUSES.

**Zonal Pelargoniums.**—Plants that have had their stems hardened through being kept dry may safely be pruned without fear of their damping. These should be placed in a temperature of 50° to 55°, and syringed once or twice daily, according to the state of the weather, to assist them to again break into growth. Very little water will be needed at their roots until they reach this stage, when they may be turned out of their pots; the old bulbs or roots reduced by one-half, and the plants again placed in the same or smaller pots. Young stock in 3-inch pots that has been preserved in good condition on a shelf close to the glass

since autumn should now be placed into others 2 inches larger. These plants should have the soil (fibry loam, one-seventh of manure and sand) pressed firmly into the pots to insure a firm sturdy growth. Those placed into 5-inch pots some time ago, and now well established in them, will move forward quickly, and very soon produce their flowers if they can be accommodated close to the glass where a temperature of 55° can be maintained with a circulation of air daily when favourable. Cuttings may now be inserted, and will root freely in small pots on a shelf in a temperature of about 60°.

*Cinerarias*.—Small plants in 3-inch pots that are not showing their flower spikes may be potted, and if well attended to will prove very useful for the conservatory during the month of May. These plants will do very well in any light airy position, in the greenhouse or in a cold vinery, until the weather is sufficiently genial to place them in frames. Supply plants in their largest pots with weak stimulants to assist them in pushing up strong flower spikes and in due time large blooms. Some care must be taken to preserve the foliage of these plants from damping, for if they do not possess good foliage when they are in flower half their beauty is gone. Those with very large flowers may be disbudded, or they have not room to develop properly, and are therefore only a confused mass when the plants have developed most of their flowers. Watch for aphides, and upon their first appearance fumigate the house with tobacco smoke.

*Primulas*.—Where it is a practice to save a little seed annually the plants should now be selected from amongst those just opening their flowers. The flowers should be removed, and the plants placed on a light shelf close to the glass, and they will come into flower again next month, and if given a little artificial manure will push up strongly. It is a mistake if a good crop of seed is required from as few plants as possible to select those for seed-bearing that have become partially exhausted by continuous flowering. Young stock for late spring flowering may now be placed into 4-inch pots. Employ a compost of loam three parts, the other part being composed of leaf mould, manure, and sand. Water carefully, and grow these plants in a temperature of 40° to 45° on a shelf close to the glass. To produce plants for flowering during the month of October sow seed at once on the surface of fine soil in a pan and place it in brisk heat. Fill the pan with light soil, and on the surface about a quarter of an inch of leaf mould that has passed through a fine sieve. Do not cover the seed, but water it with a fine-rose can after it is sown and the pan is covered with a square of glass until germination has commenced.

*Chrysanthemums*.—Where large blooms are required next autumn, or large bushes for decoration, cuttings should be rooted without delay. Select stout healthy shoots from the base for this purpose and insert them singly in thumb pots. The cuttings will root quickly under handlights in a temperature of 50°. When the young plants are rooted they should be gradually hardened and subjected as quickly as possible to cool treatment before they have a chance of drawing up weakly.

*Mignonette*.—Plants that have ceased flowering should have all seed pods removed and the shoots tied down of all that are trained upon standard trellises. These, if kept cool in a light airy position and carefully watered, will soon start again in growth, and in a short time produce large spikes of bloom. A little artificial manure should be applied to the surface of the soil to stimulate them into active growth.

## THE BEE-KEEPER.

### PURCHASING STOCKS.

Those who are intending to become bee-keepers, and who have not already done so, will now be thinking of providing themselves with stock hives, unless indeed they are content to wait and purchase an early swarm. There are several periods which are very suitable for beginning bee-keeping. Stocks can be bought much cheaper at the time of the honey harvest, but then there is the risk of wintering. Again, stocks can be bought in midwinter, and they can be bought in spring, when, however, a considerably greater price will be asked to cover the expense and risk and trouble of wintering them. Midwinter is often recommended as a suitable time, and if precautions are taken but slight objection can be raised. One thing seems to be overlooked by many who advise the purchase of stocks in the winter season, and it is this, that if bees are disturbed they gorge themselves with honey, and if they are unable after this gorging to take a flight dysentery sets in, and the stock may be lost. To avoid this risk bees should never be removed unless there is a strong probability, amounting almost to a certainty, that a fine day will soon occur to enable them to take a flight. Spring, however, notwithstanding the increased price, is the time when stocks can be bought with the least risk of loss by those who have no practical knowledge of bee-keeping.

Before concluding the purchase of a hive several points must be carefully attended to, and what these are it shall be my endeavour to show. Suppose, then, in the month of April it is intended to buy a stock. The intending purchaser should on a fine sunny day go and stand by the side of it and watch the number of bees flying in and out, and if from thirty to fifty a minute return to the hive, a large proportion of them laden with pollen, an almost certain knowledge of two facts has thus easily been ascertained. These are, that the stock possesses a laying queen, and this is proved when the majority of bees are seen carrying in pollen on their thighs, and is strong in bees. It is well, after being satisfied on these points, and if there is any doubt return another day and watch again, to ask on the chance of being told the truth whether the stock fixed on is an old one, or a first swarm, or a cast; if it is an old one, whether it swarmed last year. By these questions you will know that if the stock is an old one which swarmed last year it has a young queen; if it did not so swarm it may have an old queen, which may be so old as to be almost worthless. If the stock was a first swarm last year the queen is almost certain to be an old one, while if the stock was a cast last year the queen is as certain to be a young one. Having asked these questions it is possible to some extent to find out the veracity of the answers by gently turning up the hives and looking at the colour of the comb, which in a last year's swarm or cast will be of a light colour, while in an old stock the comb will be almost black. Other things being equal a hive containing light-coloured comb is far preferable to one containing black, because in the latter many cells are rendered useless by reason of the superfluity of pollen generally found in old stocks.

If, then, a stock can be found which has a young queen, is strong in numbers, and weighs if in a skep some 20 lbs. or 30 lbs., the purchase may safely be concluded, more especially so if the comb is of a light colour and built in a regular form. Such a stock cannot fail, with even moderately good management, to do well, and will probably, whether the owner desires it or not, unless supering is more carefully attended to than can be expected from one who has bees in his care for the first time, send out a strong swarm in May, which will be worth half the price paid for the stock. In the spring a stock must be moved at least two miles from its old stand if loss is to be avoided, and a good way to effect such removal is, if the hive is a common skep, to loosen it from its board some hours before removing it, and at evening gently lift it on to a piece of cheese-cloth, which being tightly bound round it will keep in the bees for a considerable time; and if not more than three or four miles have to be traversed a stick may be put through the handle of the skep, which may thus be carried most easily and safely by two persons, one on each side, and with the total avoidance of jerking and jolting which are sometimes so disastrous to combs when not properly secured.

With due attention to these few points even a novice may, if he is unable to get the help of an experienced man, hope, by thinking for himself and using his judgment, to avoid falling into any of the mistakes which are so often committed by men who purchase stocks merely on the word of the owner that they are sound, strong, and in good condition.—FELIX.

### THE WEATHER.

DURING the past month the weather has been more variable than I ever remember. Although the frost has never been severe, the excessive moisture after the cold but dry summer is telling hard upon *Primulas*, *Polyanthuses*, and *Alpine Auriculas*, *Snowdrops*, and *Crocuses*. My hive roofs being zinc-covered, sustain no injury from either melting snow or rain as do those of wood only, but in order to lessen the loss of bees it is advisable to restore all hives to their normal appearance. If my bees persist in flying out while the snow lies, we lift up the ladder attached to the porch, closing them in, and ventilate from beneath. Bees located in such hives will not suffer from tem-

porary confinement extending over many days, but on no account or pretext whatever should bees be shut in that are located in hives without these provisions. In such cases clearing the ground of snow well in front of hives is the best remedy, and disturb the bees as little as possible during the manipulation.

Notwithstanding the inclemency of the weather recently, a few days may usher in the beginning of the working season. In 1863 our bees collected both honey and pollen from the Snow-drop on the 24th, 25th, and 26th January, a fact not generally known, but in mild seasons Snowdrops do yield honey. Immediately after the first airing or working day, perform all necessary work in cleaning and drying the hives. In consequence of the open winter bees have been breeding, consequently in the consumption of food by the young, and in the adult consuming it for the secretion of wax for the sealing of brood cells.

Bees not very well supplied in the autumn may now be approaching starvation; attention should therefore be paid to ascertain thoroughly the state of every hive, and wherever starvation is imminent feed at once, and in such quantities as will tide the bees over till the time when there is a likelihood of the flowers yielding a supply sufficient to render feeding unnecessary, and at the same time remember that stimulative feeding, or feeding in dribblets, is a destruction to bee life during the welcome but treacherous spring months.

#### ENLARGING HIVES.

In all cases where the hives are not of a size sufficient for the laying powers of the queen steps should now be taken to enlarge those too small, as previously advised. Another thing of importance wherever supers are used is that these should be made from the whitest of wood; bees have an inclination to make their combs of a similar colour to its surroundings. Some bee-keepers use the same supers for years, and as the bees soon darken the cleanest super, that with the accumulation of colour from years' use renders the honey comb the reverse of appetising. Where the honey is used by the bee-keeper, if he is satisfied with used cases or supers nobody has a right to interfere, but in all cases where it has to go into the hands of strangers the clean super is the one that gives the most satisfaction and highest price. Cleanness and quality are the two cardinal points in bee-keeping, both as regards honey and wax. After these comes quantity, if of the first standard, which is obtained in the highest degree without the extractor, honey ripener, spreading brood, reversible frames, excluder zinc, and as many more minor manipulations. During the past fifty years, and I believe for long before, with the exception of what comb foundation has done for us in assisting the bees greatly, there has been neither any improvement in the quality of the honey nor in its quantity from single hives. Doubtless bee literature has spread the knowledge, but has not improved the quality nor the yield. Our large straw hives and Stewarton were then as they are yet, the foremost in the field. We have heard of great harvests being taken through the use of the extractor, but when the evidence came from a trustworthy source the yield did not exceed that of other well-managed hives in similar situations; but, as I have often said, that contests or competitions with bees and hives are futile unless the competition is conducted precisely under the same circumstances as to time and place.

#### WAX.

By this substance I can generally tell the quality of the honey extracted from it, and from the many samples that have passed through my hands I find that many bee-keepers have something to learn regarding both wax and honey before they can be termed proficient in their production. Enclosed herewith is a sample of wax produced from straw hives managed on the oldest system. You will observe that from its beautiful paleness the honey taken from its combs would be splendid. It presents a striking contrast to the sample marked No. 2, as sent out by a dealer in and maker of hives and wax. The production of both honey and wax of the finest quality, and in the greatest quantity, should be the aim of everyone, and we will do our best to assist all to that end, but it must not be at the expense of the wax.—A LANARKSHIRE BEE-KEEPER.

[The samples sent differed widely; one was white and fine, the other brown and coarse.]

#### TRADE CATALOGUES RECEIVED.

William Rumsey, Waltham Cross, N.—*Catalogue of Select Seeds for the Garden and Farm.*

William Bull, King's Road, Chelsea.—*List of Flower and Vegetable Seeds for 1886.*

Eric F. Such, Maidenhead.—*Catalogue of Chrysanthemums.*

Charles Sharpe & Co., Sleaford, Lincolnshire.—*Seed List for 1886 (illustrated).*

W. Piercy, 89, West Road, Forest Hill, London, S.E.—*List of Early or Summer-flowering Chrysanthemums.*

Westerham Nursery and Seed Company, Westerham, Kent.—*Catalogue of Vegetable, Flower, and Agricultural Seeds for 1886.*

H. Cannell & Sons, Swanley.—*Floral Guide for 1886 (illustrated with coloured plates).*

John Watkins, Pomona Farm, Whittington, Hereford.—*List of Seed Potatoes.*

Hogg & Wood, Coldstream-on-Tweed.—*List of Novelties and Choice Seeds for 1886.*

William Paul & Son, Waltham Cross.—*Catalogue of Vegetable, Flower and Agricultural Seeds.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Book** (*M. G., Darlington*).—Probably the work to which you refer is "Small Farms; How They can be Made to Answer by Means of Fruit Growing," by Rev. William Lea, M.A., published at this office, price 1s., or post free 1s. 1d.

**Manure** (*Young Gardener*).—We have been favoured with further notes on the subject of your letter, but our pages being full on their arrival, their publication is necessarily deferred.

**Shaded Passage** (*F. S.*).—Our correspondence is far too voluminous to enable us to remember with accuracy the contents of former letters that have been answered; but so far as we recollect the dimensions of your covered passage we think a flow and return 4-inch pipe its entire length—i.e., two lengths of pipes—would heat it sufficiently for your purpose.

**Cyclamens** (*A Novice*).—The leaves sent are some of the finest that we have seen, and there is quite as much credit due to you for skilful culture as to the strain. The flowers are of bright and pure colours, but we frequently see larger specimens. However, the strain is a good one, and it is evident you require no instructions as to how Cyclamens should be grown.

**Oncidium dasystyle** (*W. Reading*).—This Orchid is a dwarf-growing species from the Organ mountains, Brazil, and flowers in January and February. It requires to be grown in a cool house, and can be had either in shallow pots or pans suspended from the roof, where it has a pleasing appearance, the lip being somewhat suggestive of a fly or other insect.

**Names of Chrysanthemums** (*Reader*).—If you read the notes again carefully you will find that all the names are given, but we will repeat them. The top flower is Catherine-wheel, that at the right hand side is Crushed Strawberry, that on the left is Lady Churchill, and the other at the bottom of the figure is Lady Dilke.

**Pruning Flowering Currants** (*Cambridge*).—The best time to prune these pretty shrubs is during winter after the leaves have fallen and up to February. This allows of fresh shoots being made in good time, insures their ripening, and consequently flowering another season. If the bushes only need a little trimming to bring them into shape, then they may be cut in directly after flowering, and judiciously performed will not interfere much with the next season's bloom. We believe there is some such ruler or line-divider as you mention, and particulars could possibly be obtained from Messrs. Isbister & Co., Stationers, &c., Ludgate Hill.

**Starting Vines to Ripen Grapes Early in August** (*A. B.*).—To ripen Grapes at the time you name the Vines need only be started at the middle of February or even early in March, which will save much firing, as the later the starting the more the sun heat obtained, and Black Hamburgs do not require nearly so much time as the thick-skinned varieties of Grapes. A temperature of 50° at night is suitable, day temperature 55°, advancing to 65° from sun heat. If you read "Work for the Week" you will find instructions from time to time that will be useful in the management of the Vines.

**Planting Roses** (*Idem*).—The Roses that are now in the greenhouse would be better removed to a cooler place, even laid-in outside, and in case the weather continues severe cover them with straw or a good thickness of mats. This will keep them from growing, as they are likely to do if in the greenhouse. Planting should not be longer delayed than the middle of February, but we have planted them as late as March and even April in unusually late seasons.

**The Culture of Lemon Trees** (*R. C.*).—In reply to your request information, Mr. Pettigrew sends the following: "The Lemon trees here are

growing in a division of a late vinery 30 feet long. They receive the very same atmospheric treatment as the Vines at all seasons. The trees are planted at the distance of 10 feet apart, and three trees completely cover the wall. I believe the variety is the common Lemon, *Citrus Limonium*. With respect to the cultivation of the Lemon, I feel certain that it would grow and fruit equally well in an early vinery, Peach-house, or greenhouse, if properly attended to, and supplied with plenty of water both when resting and growing, and the plant kept free from scale and other insect pests."

**Petroleum for Carrots.**—*Aucubas* (A. D.).—A small wineglassful of petroleum well stirred in a gallon of soapy water has been applied to both Onions and Carrots without injuring the plants, but has rather encouraged their growth; it has not, however, proved uniformly successful in preserving the crops from maggots and wireworms, though some cultivators have found it beneficial in that respect. It might do good to give the ground a good watering before sowing. If given to the plants it should be applied to the soil alone in the evening, not sprinkled on the leaves in the morning, or the sun acting on them would prove injurious. Numbers of female *Aucubas* have green leaves, which, as a rule, are narrower than those of male plants, some being very narrow, and these plants are often the most floriferous.

**Difficulties and Poesy** (L. R.).—We regret to hear of your domestic difficulties, and applaud your endeavours to surmount them. By perseverance and industry we trust you will succeed in your object. You will find that course far more effectual than employing your time in literary exercises of the nature you have submitted. It is not quite suitable for our columns, and we should not be advising you well if we encouraged you to send it to any of the London general papers. You can, if you like, send it to a local editor, though we know pretty well what his decision will be. When men of experience and education fail in making this kind of work profitable you cannot hope to succeed. Let it alone, and persevere in your work in establishing a business in which you may make a comfortable livelihood.

**Pyracantha not Fruiting** (A. M.).—No doubt a want of sun first to ripen the wood in autumn, then to dry the pollen in spring, is the chief cause of your plant not fruiting. The only thing you can do is to remove any luxuriant growths that shade and overcrowd others of a shorter-jointed and sturdier character early in August, so that these may be as fully exposed as possible to light and air. Then when the flowers are expanded and quite dry shake the sprays a few times—or, rather, once a day for a few days—to assist the dispersion of the pollen, and fruit may possibly follow. By all means train the branches round to the sunny side of the building, and if not overcrowded they will be almost certain to produce flowers that will be followed by clusters of fruit.

**Pancratium Roots Dying** (W. J. C.).—It is not possible for us to inform you what has caused the decay of the roots, as we are quite unaware of the treatment the plants have received, or the conditions under which they have been grown. A check, such as from cold, an excess of water or liquid manure might cause it, or the bulbs may have been attacked by some insect. This can only be determined by examination; but whatever the cause of the injury we should shake the bulbs out, wash them, place in fresh rough compost containing a liberal admixture of charcoal, place in rather small well-drained pots, plunge them in bottom heat, and treat generally as we previously advised for *Eucharises*.

**Tanks for Rain Water** (W. M.).—You are acting wisely in making provision for the storage of all the rain water you can under the circumstances. We are very similarly situated, and have constructed tanks which afford us an unfailing supply. They are lined with cement, and the water is conducted to them through glazed earthenware pipes. Though it may be a little hard at first, when the tanks are new, this soon passes off and the water is as soft as can be desired. The price you name is, we consider, fair. A cubic foot contains a trifle over 6 gallons. You have no occasion to apologise. We do not feel "bothered" at all when we can impart information, but we cannot account for the water in your tanks turning hard. All we can do to aid you is naming the conditions under which that in our tanks remains soft.

**Repotting Hoya** (H. T.).—If you have not a warmer house into which you can stand the plant after potting, we should wait a month or six weeks before disturbing it, or until your house is naturally warmer in consequence of the increased external temperature. It should not be less than 50° at night, with an increase of 30° in the day by sun heat, for starting the plant into growth. The pot, we should imagine, will be abundantly large enough, perhaps larger than is needful; but all depends on the roots. We should not be surprised that when you examine the roots you will find some of them dead; if so, these must be removed and all inert or sour soil removed also. The pot should have a depth of at least 3 inches of drainage, this to be covered with a layer of fibre from which all soil particles have been beaten or shaken. A suitable compost will be two parts of turfy loam, one part of turfy peat, and a tenth part consisting of crushed brick, lime rubbish and charcoal, all to be well mixed. This should be well worked amongst the roots, dividing them as much as possible—that is, not pressing them together in a mass; then make the soil moderately firm, but not hard, and give a good watering with tepid water. Afterwards be careful not to saturate the soil by over-watering, but rather keep the plant fresh by syringing it once or twice a day, according to the weather, and especially early in the afternoon when the house can be closed with a good sun heat. If the roots are much disturbed in the process of potting afford shade from bright sun by a screen of paper or other light material affixed over the plant. With judicious attention in watering and syringing it is almost certain to recover, and the leaves change from a sickly yellow to a deep green hue, and when this occurs more water will be needed at the roots and full exposure of the foliage to the sun.

**Potting Ferns** (*Idem*).—If you add a handful of leaf soil to the above compost it will be suitable for both the *Davallia* and *Platynerium*. The latter is often grown on blocks similar to *Orchids*, the plants being affixed in a cavity containing some rough soil. We have, however, seen very fine specimens grown in pots. Half fill the pots with drainage and affix the plants on a mound slightly above the rim. The *Davallia* should be potted rather high also, so that the rhizomes may spread over the rim. Thus potted abundance of water can be given when the plants are growing

freely with little danger of rendering the compost sour—a point of considerable importance in the cultivation of these Ferns.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. —(J. C.).—1, Bess Pool; 2, Baxter's Pearmain; 3, Ord's; 5, Reinette de Caux; 7, Blenheim Pippin; 8, Scarlet Nonpareil.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (W., Reading).—The flower was not in good condition, but we believe it is *Oncidium dasystyle*. See reply above.

## COVENT GARDEN MARKET.—JANUARY 27TH.

BUSINESS somewhat quieter. Best samples of Grapes improved. All other goods unaltered.

### FRUIT.

### THE FLOCK.

HAVING regard to the importance of early maturity in sheep, we may usefully consider now, before lambing becomes general, what may be done not only to bring lambs upon the

market as speedily as possible, but to bring them there in the highest condition consistent with economy. In doing this we may inquire what has been our purpose in sheep-breeding, or, if we have had any special end in view other than that, of obtaining as many lambs as we could. Looking through an ordinary flock of sheep we generally find many inferior animals, and if we talk to the shepherd he will point out others with some blemish or fault that should have led long ago to their expulsion from the breeding flock. It is only by careful selection and equally careful breeding that we can gradually form a really good flock. The history of any famous flock shows this clearly, and it ought certainly to be our ambition to effect some annual improvement among our sheep. It is plainly our interest to do so, and in order to do this well we must be much among the sheep, especially on the approach of and during lambing.

Debility should never be passed over lightly, especially when there is evidence of it in parturition. A ewe that is long in labour, suffers severely from straining, or cannot bring forth its lamb without assistance, ought not to be let breed again. The birth of a dead lamb is not altogether to be taken as an indication of debility on the part of the dam, the loss of the lamb being attributable to fright, or to some injury arising from over-driving or jumping. We have now several fine young ewes kept apart from the flock simply because of their propensity to jump over every fence, an ordinary hurdle being a trifle to them, and the shepherd assures us they can easily clear a five-barred gate. To attempt such leaps when heavy in lamb often leads to some catastrophe, and the tendency to jump over enclosures should be checked as much as possible in its infancy. This is best done by keeping "jumpers" in some high enclosure till the habit is forgotten; or rather to place would be jumpers there before the habit is acquired and becomes fixed. Debility often proceeds from a severe cold; we have lost both ewe and lamb from such a cause. Surely the fact of severe coughs and colds being so common among animals having such a warm natural clothing as sheep points to an undue amount of exposure and a want of adequate shelter. If an entire flock became affected shelter would then be provided, yet why should some of the sheep suffer for want of due care on our part? Or to put it in a more practical manner, why should the farmer run the risk of losses among his sheep from any cause which it is in his power to avoid? It by no means follows, however, that weakly or half-starved sheep fail in lambing. The half-wild sheep on Ashdown Forest in mid-Sussex afford a remarkable example of this. In winter these sheep are in sorry plight, being kept in a state of semi-starvation; yet there are plenty of lambs every spring, and though small they are active and healthy.

Some ewes will not suckle their young ones, either pushing them away or knocking them down whenever they approach the udder. With care this propensity may frequently be cured; when it cannot be cured the ewe is condemned, and marked for draughting for the butcher. So, too, are all others with any serious defect, and it is by this careful weeding of the flock every year, and by additions of well-chosen young ewes, that much good work is done. The assertion that the progeny of ewe lambs come to maturity sooner than that of older sheep must be received with some caution, for we do not put our ewe lambs to the tups till a month or more after the older sheep, and an early February lamb, if well cared for, ought to be ready for market sooner than one born a month later. No doubt breed tells in this matter, but then care and pains in management tell also. Well-fed ewes give strong lambs, and highly fed lambs, suckled by a vigorous well-nurtured ewe, thrive apace. There must constantly be a full generous diet for the ewes, and a progressive well-considered one for the lambs. Let there be no sudden change from poor to rich food. As the ewes lamb they are gradually brought with the lambs on to sound and, if possible, an upland pasture. Lambs soon begin eating gra and with growth and age even before the weaning, they ta

dry food, such as bran, crushed Oats, and crushed Waterloo cake. When they consume dry food freely and with evident relish they make rapid progress, the most forward soon passing into the grade of fat lambs, and are early in the markets. Those intended for store sheep are not generally so well fed; yet it is wrong to allow them to fall into poor condition. Ewe lambs well fed grow fast, and are ready for the tup in October, our generous treatment being well rewarded by an early crop of lambs. Wether lambs are also fed so well that by the time they enter the Turnip folds in winter as hoggets they have large and by no means badly nurtured bodies; they then make rapid progress upon Turnips and trough-feeding in folds. We recently went to inspect some of our hoggets in such folds and found them progressing satisfactorily, for they were to remain on the land till March, passing on from fold to fold, and the ploughs were in full swing turning over the land closely after them, in readiness for the Barley sowing.

#### WORK ON THE HOME FARM.

Much draining has been done, both with 2-inch pipes and bushes, and we have made arrangements for doing a few more fields. We came to this decision while walking over the land some twelve hours after a heavy downpour of rain, and found the soil so thoroughly saturated that we sank over our boots in the soft soil. Now this is what is termed "good mixed soil," having so many small stones among it that superfluous surface water must pass quickly through it to the subsoil; but a clay subsoil must be opened by drains, or the water enters it so slowly that the soil becomes water-logged. We found the new bush drains answering well, a full strong flow of water running freely from every one of them. Bush drains are efficient for six or eight years, when they must be renewed. In a field where this is being done, the old drains were made diagonally, and by making the new rectangular drains across them we tap the old drains, and thus add to the efficiency of the new ones. We commend bush-draining to the attention of our readers both for its economy and efficiency; the drains are 30 yards apart, and about 30 inches deep, and they answer perfectly to relieve all land quickly of surface water, but they are not intended to supersede deep tile drains, which, at a depth of 4 feet, have an important double action in draining the surface water, and in checking the rising of water to the surface by capillary attraction. In draining chalybeate springs pipes should never be used, for they invariably become choked by an ochreous deposit, which, though it adheres to the bushes, does not prevent the passage of water among them. This is another of the many instances which occur in practice to show that we cannot always go by line and rule, but must adapt ourselves to circumstances as they arise. Though a simple process, draining is by no means to be done without due thought, and we may add without ample evidence of its necessity. Light sandy soil upon an open subsoil is drained naturally—over-drained, it may be said to be, for crops suffer severely in it during drought. All soil containing many small stones or much hard gritty matter affords a free passage to surface water, and we have to see that the subsoil has also sufficient mechanical division to allow water to pass away quickly through it; if not, we must open it with drains at such depths as appear best for each particular piece of land. Look closely into the condition of old drains. If ditches are not cleaned out regularly an accumulation of leaves and rubbish gradually gathers over the mouths of the drain, which thus become choked and useless. There should be a grating over the mouth of all pipe drains larger than 2 inches to keep out rabbits and other vermin.

#### REMARKS.

- 17th.—Fine pleasant day; dull evening.  
 18th.—Fair morning, fine bright afternoon, clear cold night.  
 19th.—Fine morning, freezing hard, but foggy; snow at noon.  
 20th.—Foggy early, then fine and bright.  
 21st.—Snow from early morning till 10 A.M., and at intervals till noon; dull cloudy afternoon.  
 22nd.—Overcast morning; fine afternoon, with a little sunshine.  
 23rd.—Snow early, and sprinkling with slight rain all day.  
 A cold snowy week, with constant low barometer.—G. J. SYMONS.

### MUSCAT OF ALEXANDRIA GRAPE.

**S**O much has been written about this Grape that it may be thought that nothing new can be advanced regarding it. Such may be the case, but I would venture to say that the Journal is always having added to its numerous readers young men just beginning life as gardeners who have not read all that has gone before on Vines and other horticultural subjects. There are also always new readers being added amongst the amateurs, and some of them may perhaps find the following notes of use; at any rate I offer them with that hope.

First of all it may safely be said that Muscat of Alexandria is a grand Grape which should be grown by all who wish for high-class fruit. It is well worth the additional trouble sometimes required to have it in perfection, and those who are successful in its culture are always found extolling it in every way.

Mr. Thomson of Drumlanrig, in the Journal for January 21st, gave some interesting notes on the Muscat and his experience with it in some past seasons. For some years Muscats proved far from satisfactory at Drumlanrig, where all other varieties were to be seen in first-rate condition. Mr. Thomson attributes the unsatisfactory condition of the Muscats to the want of sufficient drainage in the border, and I am inclined to think he is right. The measures he took to cure the evil of a too deep and insufficiently drained border he describes, and also the yearly improvement that has taken place in his Muscats since the border was made more shallow and more perfectly drained. The experience I have had with Muscats entirely coincides with Mr. Thomson's. Shallow well-drained borders, where abundant water could be given—where, indeed, the surplus water from each watering could at once be seen running out of the borders, they being quite above the level of the surrounding ground—seem to suit the Muscat exactly, provided always abundance of water be given when that is required, whether from the borders being inside or in dry weather if outside.

Nothing is more calculated to prove disastrous to the welfare of Muscats than too deep and ill-drained borders. Much time, labour, and expense have been laid out on Vine borders sometimes, which is very ill requited, in regard to Muscats at least, for the simple reasons that the borders are made without enough drainage and also too deep. Give me a shallow border above the level of the ground, an abundant supply of water, plenty of good soil and manures to top-dress with every spring, and, other things being favourable, Muscats will thrive and fruit as freely as can be desired.

Regarding the varieties of Muscats much uncertainty prevails, and men of great skill and experience take entirely different views on the matter. Bowood Muscat has never been seen by the writer so distinct as to warrant its being cultivated under a different name. Indeed the difference was more imaginary than anything else, as, knowing that what was called Bowood was being looked at, some slight difference was thought to be observed, and that is all. Grown side by

side with other Muscats, I have not noticed it any earlier than other varieties. There can, however, be no mistake in saying that Canon Hall Muscat is a distinct variety, and when successfully grown it is a splendid Grape in appearance and in quality. It is, however, extremely fickle, and too often rewards its cultivator with a long straggling bunch with a few scattered, properly set and swelled berries, and this after careful attention and artificial fertilisation.

In order to attain success in the culture of Muscat of Alexandria, in addition to shallow well-drained borders and plenty of surface feeding, I would advise that the rods be kept so far apart that all the laterals may be tied out at right angles to the main stems, so that the foliage may receive every chance of catching as much sun as possible, and that the wood may be thoroughly ripened, which does not happen sometimes, when shoots are too thickly laid in and the leaves unduly crowded.

Never be tempted to crop Muscats too heavily. The difference between Muscats which have been cropped so that they could finish their fruit well, and others which have been overburdened, is so great that nothing should induce anyone to overcrop. In the one case well-ripened, well-swelled, and perfectly finished Grapes can be had; Grapes which will keep a long time and be a pleasure to eat. In the other case want of colour and finish, early signs of shivelling, and a great want of flavour and sweetness result. Some cultivators advocate leaving the bunches so free from leafy covering that they will get the direct rays of the sun, but I have found that this causes scalding at the stoning period, and also turns some of the berries into raisins later on. If the Vines are in good order and not too heavily cropped, the bunches will colour quite golden beneath a moderate amount of foliage, and then scalding and roasting into raisins can be avoided.

As a general rule it is advisable to use artificial fertilisation to secure a good set with Muscats. When the bunches are in bloom they should be brushed over very lightly with a feather or foxtail, choosing midday for the operation, at the same time endeavouring to maintain a temperature as near 90° as possible, with a circulation of air when such can be safely obtained. On some cold days in spring, when the sun is powerful, raising the heat in the houses considerably, and when at the same time an east wind is blowing that chills everything it comes in contact with, it is extremely difficult to ventilate houses where Muscats are in bloom, so that a circulation can be maintained without a chilling effect. This is one of the many difficulties a gardener has to contend with. In dull cold weather pipe heat must be resorted to, to maintain a temperature as near 80° as possible, and assiduous attention must be paid to the precious Muscats in the way of applying the feather or foxtail so that every bunch may be caught at the time when its pollen is ripe and ready. Nothing is more disappointing than a bad set of Muscats, as the labours of a season must then go in a great measure unrewarded.

In comparatively sunless summers it is often very necessary that much fire heat be used in conjunction with a judicious ventilation, in order that Muscats may be sufficiently ripened to enable them to keep well. When such is the case red spider too often appears. When first observed I advise an immediate attack with clean water and the syringe. Taken in time the red spider may be checked, but allowed to get a hold it is certain to make its mark before being overcome. Sulphur is thought by some to be effectual in checking red spider, but sometimes it is very doubtful whether the maintenance of a dry, or at least a comparatively dry, atmosphere at a time when plenty of moisture is beneficial, is not more calculated to enable the pest to thrive, in spite of sulphur, than if extra moisture and syringing were resorted to.

Mildew, generally the result of a too stagnant and damp atmosphere, is another trouble that sometimes affects Muscats seriously; but in most cases it might easily have been avoided if due attention had been paid to atmospheric con-

ditions. Sulphur dusted on the leaves and painted on the pipes is sometimes resorted to in order to check the ravages of mildew; but I would say in this case as in others prevention is better than cure. Shankling may be caused by overcropping, sour borders, or sudden checks, and it should be the endeavour of all cultivators to avoid all these evils.

The question of the temperature necessary for the proper culture and ripening of Muscats has been in past years the subject of much controversy, some writers maintaining that they can be properly ripened under a cool system, and others—and I think the majority—maintaining that an extra amount of heat is required to properly finish all Grapes belonging to the Muscat family. The experience I have gained makes me decidedly of the opinion that heat in an extra quantity is required for the ripening of Muscats. This has sometimes prevented people undertaking their culture, but I can assure them that the extra heat and care required will be well repaid, for a quantity of Golden Muscats is the result. Taking it with all its peculiarities and extra requirements, this Muscat is a king among Grapes; it always commands due homage when displayed in regal splendour, and the many votaries of Horticulture who attend the numerous exhibitions throughout the country are ever ready and willing to express admiration when this Grape is exhibited in prime condition. We know that some hesitate to attempt its culture through fear of not being able to provide some of its requirements, and to aid these the foregoing notes have been penned.

For packing and standing a railway journey the Muscat is first-rate, as it also is for the dessert table. Its keeping qualities are of the best, and altogether it combines such excellent and valuable qualities that no one should rest contented who cultivates Grapes and has not successfully grown the noble Muscat of Alexandria.—Hortus.

#### THE PLEASURE AND PROFIT OF AN AMATEUR IN VEGETABLE GROWING.

THE heading was written easily enough, but now how to go on I scarcely know. I feel that much may be written, but not having the fluent pen of "D., Deal," I fear that I cannot do justice to my subject.

Some ten years ago when, living in the country and fresh from London, with a small garden attached to my house, I felt that it would be healthy amusement to do my own gardening. This was the commencement of my interest in horticulture, and my first Potato planting followed. I was soon anxious to see the product of my labour—too anxious indeed, for I began lifting when the tubers were but the size of marbles. I was thus taught that patience was required, but my heart was in my work, and I soon managed to have a constant supply of fine vegetables in my garden, obtaining thereby credit from my friends and satisfaction to myself. Of course this increased my desire to do better, and the taste grew on me, as it always will on others, so that I began to think of exhibiting. My first attempt was a failure, but I now manage to take my fair share of prizes in the vegetable and fruit classes at the local shows. Year by year I try to produce something better than the year previous. As in my case so is it in others. You begin to take a slight interest and dabble in the garden, and it soon grows into a never-ending pleasure to you. Raising seedling Potatoes, new Melons, or Cucumbers never fails to give satisfaction to the man who loves his garden.

Turning to the Brassicas, I believe that there is an open field for amateurs with plenty of time, patience, and perseverance into which many may tread. Peas, Potatoes, and Beans are so good now that we cannot hope for much better; but if Mr. Gilbert can produce not only an entirely new vegetable in the famous Chou, but improvements on existing varieties, such as Victoria Broccoli, Chou de Gilbert, and Universal Savoy, is it not possible that some other vegetables may be produced by careful and persistent experiments? For instance, a Sprout bearing miniature Cauliflowers all up the stalk in the place of miniature Cabbages, as in the Brussels Sprout. Surely it is possible. I find that fine Cauliflowers, of which I may feel proud, do not find acceptance in the kitchen, but hints are thrown out that smaller produce is better for the table, so why cannot we try to produce them small, but in great abundance, on one stalk? I believe there are no bounds to Nature's possibilities when

assisted by man's care and patience. How I envy floriculturists What a boundless field they have.

After all this rigmarole you will naturally ask, What is the profit? I added above "of an amateur." As a profitable undertaking in a monetary sense I will not venture to give an opinion in these bad days. The profit I allude to is the employment of your mind in a groove far removed from your everyday business cares and domestic anxieties, combined with physical labour of the healthiest kind, which will go far to give you an enjoyment of your meals, and an elastic feeling of superabundant energy. What other pleasure, what other hobby, what other occupation will pleasurably employ your mind and healthily exercise your body? None, save horticulture. How you can enjoy sowing the seed, watching the crop gradually growing to maturity, and when ready for use do not your own vegetables, which you have yourself tended, taste far better for the interest you have taken in their production?

I do love my garden, and I heartily thank our Editor and our Journal's contributors for fostering the love of horticulture in the hearts of so many of their readers.—H. S. EASTY.

#### CARNATION MISS JOLLIFFE.

THIS is now a comparatively old variety, and is so well known that to praise it would be superfluous. I shall therefore endeavour to point out some qualities which may have escaped the notice of some of its admirers. It is so well known as the best variety for supplying flowers during the darkest days of winter, that its value as a flowering plant at other seasons may well be overlooked, especially when the ordinary method of propagating young stock every spring with the concurrent dismissal of the old plants to the rubbish ground forms the general method of culture. If those who have healthy plants of this Carnation flowering, say in 6-inch pots, will take care of them, placing them into 8-inch pots in April, the blooms these will provide in early summer will be most valuable. They do moderately well in the same 6-inch pots, but as compared with the shifted plants these are much inferior. And the same plants will continue flowering more or less all through the year. Indeed, the most floriferous plants in midwinter we have seen have been some of these plants so treated. I like to grow them in good loam and cowdung, and when they reach the period for extra food to be supplied it is regularly given them.

Reverting to these as summer-flowering plants, it may be added that they are excellently fitted for arranging amongst Pelargoniums and other greenhouse plants, while for furnishing vases of cut flowers few can excel them. A good branch ought to produce four good blooms at the point of the shoot and several smaller blooms down the stem. These cut the full length of the stem make quite a feature in an arrangement of cut flowers.

The best time to propagate this and other Carnations is not in spring in heat, but in summer. Sturdy side shoots taken off in July, inserted in the open garden and covered with handglasses, strike very freely. An efficient method of shading these handglasses is to dip each one into water, then sprinkle fine sand over its inner surface before it has had time to become dry. This shading will last good in all kinds of weather until it is removed. When the cuttings are rooted the handglasses are removed and the plants left to grow until September, when they are placed into 3-inch pots and left out of doors until the middle of October, when a cold frame is the best place for them, in which they remain until spring, of course plenty of air being admitted in favourable weather. All varieties of tree Carnations are best propagated as above. The variety *Souvenir de la Malmaison* strikes with certainty, and strong plants are secured to begin with the spring, as those which escaped pinching in the autumn are ready at this season, many of them bristling with growths close to the base ready to advance with the return of genial weather.—B.

#### THE BEST MELONS.

NEARLY every grower has his special favourites, but it does not follow that these are best for all persons, one reason for this among several being the important fact that so much depends upon the conveniences of the cultivator, as well as the taste of those for whom the fruit are grown. At the same time, a few remarks on the various sorts that have come under my notice may be of service to intending cultivators who may yet be undecided as to which to select. The Committee of the Royal Horticultural Society undoubtedly adjudicate impartially upon the many seedlings submitted to them, but after all it is by no means certain that the certificates are awarded to sorts that are likely to become popular. The raisers fully understand the

habit of growth and other characteristics of the sorts they submit for certificates; not so the Committee, who, if the fruit happens to be distinct in appearance and good in quality, honour it with a certificate. When the seed is distributed each packet may contain several forms, and the cultivator is disappointed accordingly. The fruit, not the variety, awarded the certificate may have been the result of an accidental cross owing to the close proximity of other sorts, and as a consequence the official recommendation may after all prove misleading. Those who save seed for distribution especially ought to most carefully guard against this. No other variety ought to be in the same house, then we should hear fewer complaints of certain varieties not being at all equal to the glowing descriptions. As it is, plenty of gardeners have discontinued purchasing Melon seeds, preferring rather to procure them from friends who can supply them true to name. Further, those who, like myself, have been fortunate enough to obtain good stocks of certain reliable sorts, carefully preserve and continue to annually sow a few seeds from the same packet. We do not rely, however, upon old seeds, new seeds being the most likely to give the strongest plants.

Longleat Perfection, a new variety obtained by Mr. Pratt at Longleat from a cross between Eastnor Castle and Hybrid Cashmere, is undoubtedly distinct and first-class in quality. As only this novelty and its two parents are cultivated at Longleat, there is not much danger of the stock becoming deteriorated, and I have not the slightest doubt it will figure prominently on prize lists throughout the country. I should say it will not succeed well in frames, neither must it be closely stopped in houses where canker is apt to be prevalent. No comparatively new variety equals Hero of Lockinge for all purposes, this well-known sort being alike suitable for frame and house culture, while the fruits are handsome enough for collections of fruit, and good enough to win prizes in the classes provided for Melons. It keeps and travels well, and provided the plants carry a good crop the fruits are of the right size to please the fruiterers. The latter, with whom too many gardeners now have business, do not thank them for sending large Melons, those ranging from 2 lbs. to 3 lbs. usually selling the most readily.

Eastnor Castle, when it can be obtained true, is a free-bearing sort, the fruit being large, handsome, and of the best quality. As a rule, spurious forms only can be obtained, and the fruits of these are usually large and ugly. Webb's Woodfield also possesses some of the characteristics of Victory of Bath, from which it was doubtless obtained, but with us the fruits were somewhat rough in appearance—were much too large, in fact. It has been a favourite variety with exhibitors in the west of England, and several first prizes were awarded to it. I intend to grow it again. Golden Perfection is one of the prettiest Melons in cultivation, particularly good for collections, and sometimes being also of good quality. William Tillery appears to be losing ground, but I do not think it would have done so if it had been kept true. Burghley Pet is the favourite sort with a gentleman near here. It is a heavy cropper, and the fruits small in size, are handsome, heavy, and good in quality. This is well worthy of a trial either for marketing or where small fruits in plenty are required. The old Golden Queen, if it can be procured true to name, is one of the best for frame culture, and a capital sort for the market.

Among scarlet-fleshed varieties Blenheim Orange is still pre-eminent, and I should say it would be impossible to raise one more serviceable. I am constantly recommending it as the best companion for Hero of Lockinge, whether for pot, house, and frame culture. It is one of the first to ripen, and after it has been kept for three or four days in the fruit room it is greatly improved in quality, winning prizes innumerable. The largest and most handsome fruits of this I have yet seen were in a gentleman's garden at Frome. It has largely superseded Read's Scarlet Flesh, although the latter is by no means to be despised, and is still grown by a few. Scarlet Premier rather disappointed me, the quality not giving satisfaction. It is free-bearing and handsome, but on the whole not so good as Lunefield Hybrid, a variety somewhat resembling Premier, raised by Mr. E. Burton, the gardener at Lunefield, Kirkby Lonsdale. We found this novelty all that the raiser informed me it would be—viz., free-bearing, of good weight, or from 4 lbs. to 5 lbs., thin-skinned, and fine-flavoured, it was the most profitable of all the Melons fruited in pots early last season. Sutton's Masterpiece is also a first class scarlet-flesh, and good for all purposes. As a rule green-fleshed varieties are preferred by judges at horticultural shows to the scarlet-fleshed, but I am inclined to think prejudice has something to do with it, as I have tasted the last-named and Blenheim Orange equal to any green-fleshed variety in general cultivation.

Our friend, Mr. G. Abbey, has been successful in raising

several very excellent sorts, but does not appear to have made capital out of them, yet I feel certain if he selected his best and distributed them they would become great favourites, as they are no chance crosses, but were the result of much pains to secure varieties possessing good constitution and free-bearing habits, high quality being also duly considered. Very few gardeners are so well versed in Melon lore, and his experience related in the *Journal of Horticulture* would be instructive.—W. IGGULDEN.

## CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 68.)

### SPECIAL TREATMENT FOR WEAK VARIETIES.

SOME varieties of Chrysanthemums are much weaker in constitution than others, consequently they require rather more care to develop their qualities than those of a more robust habit. Some of them are handsome in form, and their general good quality renders them indispensable in a first-rate collection. By a judicious course of treatment the difficulty attending the successful culture of weak varieties can be overcome. For the guidance of those persons who do not know the varieties referred to as weak growers, I have compiled a list of them, and detail the method of managing the plants, which I commend to the special attention of the inexperienced. The list comprises only those which are meritorious and worth growing.

As previously stated, propagation should commence with these as early as possible, so as to give them a long season of growth and to avoid undue excitement, such as forcing them in heat to make up for the time that is lost by striking the cuttings late. At the first potting from the cutting stage place the plants in 3½-inch pots, adding half a part more of leaf soil to the compost previously advised. Treat the plants in the same way as the general stock as regards position and watering. When they are ready for the next shift, which should be into 5-inch pots, the soil should be the same as before. From these they can be transferred into their flowering pots, which should be 8 inches in diameter. The soil used in potting them finally should be of a lighter kind than that used for those of stronger growth. The following preparation is suitable: To three parts of half-decomposed fibry loam add one part each of half-decayed leaves, used in a rough state, and the materials of a spent Mushroom bed, half a part of wood ashes, the same quantity of fine ground bones, one part of coarse silver sand and charcoal broken about the size of Hazel nuts, the quantity to be in proportion to the nature of the loam, be it light or heavy. This materially aids in keeping the whole porous—a point of much importance during the summer, when water must be applied at times copiously. If the loam is of a strong nature the fine soil should be taken out by passing it through a sieve, retaining only the fibrous parts, as the fine soil prevents to some extent the free passage of water from the roots. The pots should be very carefully drained, and the soil pressed firmly around the roots, but not quite so hard as in the case of the stronger growers, weak varieties not making roots in the same proportion as the others. The great point, then, is to prepare suitable soil, have the pots of the right size, treat the plants judiciously with regard to watering in all stages of growth, and satisfactory results may be anticipated, if other requisite details in treatment are carried out. It is a good plan to stand these plants by themselves during the summer, as they are then more directly under control, and are not so apt to be overlooked as when placed among the general collection. Stimulants should not be applied to them in the same quantity and strength as to those of more vigorous constitution.

The following varieties need the special treatment indicated:—

JAPANESE.—Balmoreau, Criterion, Golden Dragon, Garnet Agreements de la Nature, Japonaise, J. Delaux, Margaret Marrouch, Madame de Sevin, M. Ardene, M. Astorg, Mons. Tarin, Mrs. Mahood, Mr. John Laing, Sceptre Toulousain, Beauté des Jardins, and Mons. H. Jacotot.

INCURVED.—Barbara, Cherub, Empress Eugenic, Lady Carey, Lady Hardinge, Mr. Bunn, Mrs. W. Shipman, Nonpareil, Princess Beatrice, Sir Stafford Carey, Angelina, and Lady Slade.

ANEMONES.—Fleur de Marie, Mdlle. Cabrol, Madame Clos, and Sœur Dorothee Souille, to which may be added the two reflexed forms, Dr. Sharpe and Empress of China.

### HINTS ON GROWING NOVELTIES.

Some growers of Chrysanthemums have a strong fancy for "novelties," and are induced to procure nearly all the new varieties as fast as they appear. I say nothing against experienced growers indulging in this floral luxury, but the inexperienced cultivator who is desirous of forming a first collection may easily err in this respect. He sees the descriptions of so-called novelties, and assumes they are improvements on older varieties. This by no

means follows. They may be distinct without being superior; indeed, I venture to say that quite three parts of the new sorts sent out in such glowing terms are not equal in merit to many of the older varieties. What I wish to impress upon beginners is this—Do not rely on catalogue descriptions entirely, which are in the majority of instances copied from French raisers, and the colours as set forth are not always to be found in the flowers produced; and never buy a variety without first hearing something good of it from someone who knows its merits and has nothing to gain in describing them, for it is an assured fact that if a new variety has the necessary qualifications it will not remain long in seclusion. No little disappointment has been caused by purchasing all the new varieties which were expected to produce wonderful flowers. Instead of this it has often been found that time and space have not been well occupied in growing them. Far better is it to grow an extra number of plants of those varieties which experience has proved can be depended upon as certain producers of first-class flowers under first-class culture, than for a grower with limited experience, money, and space to overburden himself with so-called "novelties." If those persons who are responsible for the descriptions of new varieties were to adopt a much more simple way of describing their qualities they would be doing a public service, enabling growers to purchase the new sorts with much more confidence than at present.—E. MOLYNEUX.

(To be continued.)

### THE CULTURE OF PEAS.

WEATHER permitting, I shall make my general sowing of Peas this week, both for profit and exhibition, and shall continue making small sowings about every fourteen days afterwards for late shows or culinary use. I shall make sowings of the varieties previously recommended, and from them shall be able to choose Peas of sufficient merit or quality either for a collection, a single dish, or for culinary use. As the Peas grow I keep gradually earthing them up until they are from 4 to 6 inches in height, then I commence placing sticks to them about 12 inches long. When the Peas have grown to the height of these sticks much longer stakes are employed, according to the height the Pea is supposed to grow. Each row is carefully examined, and wherever the plants are closer than 4 inches apart I draw the weakest out. If the Peas are required for exhibition I watch and carefully train them, tying the haulm to the stakes with matting; in so doing I save many a good pod that I am able to use for exhibition which would otherwise have been broken by strong winds.

When the Peas have flowered and commence podding is the time to decide whether they are intended for exhibition or profit; if for the former, as soon as the peas are formed in the pods pinch off one of each pair of pods and leave the others growing singly. By so doing the pods will be nearly one-third larger than if left to grow in pairs. When the Peas commence swelling and I think they require a little liquid manure, I take the garden spade and raise the soil about 3 inches each side of the row and round the ends, so as to form a small shallow reservoir, into which I pour the liquid. Peruvian guano is sometimes used, about one handful to two gallons of water. You need not be afraid of killing the Peas with liquid manure of any kind, as I have found from experience that it is almost impossible to do so. Give them three applications of liquid a week; they will only require it for about two weeks, unless the weather is very dry and hot, and then I use it much earlier, as I find it does in the place of watering, and of course is much more stimulating to the plants. When you commence using the liquid manure no more lime will be needed, as the slugs have a great disliking to guano.—HY. MARRIOTT.

I AM fully aware Mr. Marriott is a most excellent cultivator, but with one exception I should not advise sowing the Peas he names at the present time. I find from many years' practice that you cannot sow wrinkled Peas with safety before the first week in April, and the majority of those he names are wrinkled. Evolution, being a blue round Pea, can be sown at the present time, but I should very much doubt if any of the others would be a success. These Peas I should average would cost 5s. a pint round, and the expenditure of 40s. for eight pints of Peas, sowing them all in one day, would scarcely be prudent in ordinary practice.—KITCHENER.

### A USEFUL MANURE.

In your most valuable paper of 31st of December last Mr. J. Swan calls our attention to what he designates "a useful manure." The plants for which it is by his account so well adapted are amongst those I am striving to cultivate satisfactorily; and his success makes me wish to prove the power of the manure, but I fail to properly understand this method of mixing it. When he says, "If having a quantity of night soil on hand mix it with half the bulk of the earth," does he mean half as much burnt material as night soil? Secondly, in what proportions would it be advisable to use it for the plants he mentions? how much to a barrowload, or any quantity larger or smaller? The Melons and Cucumbers, he gives us to understand, can be grown in equal parts in pots. Your kindness and able advice in the past encourage me to apply again in the hope that I may meet with similar treatment.—YOUNG GARDENER.

[In reply to the letter from a "Young Gardener," I may say he has

correctly defined my meaning in reference to mixing the manure—namely I recommend half as much burnt earth as night soil. When left to accumulate in an exposed state it is not so effective as the same quantity of manure when mixed at once with the burnt earth owing to the loss of nitrogen by evaporation. For *Celosias*, *Cockscombs*, and *Gloxinias* I use the manure at the rate of one barrowful to two of loam, and for *Zonal Pelargoniums* and *Balsams* equal parts of manure and soil. The latter luxuriate in the above mixture without any leaf soil. We grow ours in 6-inch pots, and the plants become extremely large and floriferous, some of the flowers being 3 inches across, and if not allowed to seed they will flower for three months. I recommend potting firmly, as the burnt earth has a loosening effect on the soil.

For Chinese *Primulas* the compost consists of one barrowload of light soil, three of loam, and a half barrow of leaf mould; but the soil is only part of the means to secure success. I treat my *Primulas* as follows:—I sow the seeds about 15th March in pans well drained and filled with a mixture of equal parts of loam, leaf soil, and powdered charcoal, cover the seeds with the latter; and I find they germinate more strongly out of the charcoal owing to the ammonia supplied by the same. They are lifted with the roots clinging tenaciously to the particles of charcoal, and are scarcely checked in removal from the seed pans. I dip the pans when water is required in preference to using the watering can, and plunge them in a temperature of 65°. When the seedlings are up I put the pans on a shelf near the glass to keep the young plants sturdy as possible, for if weakened in the pans nothing will make up the deficiency. As soon as they have made four leaves they are pricked out in boxes 2½ inches deep filled with a mixture of one part of night soil to two each of loam and leaf soil. With some half-decayed leaves (Beech if possible) the soil is pressed firmly and watered, and when nearly dry the seedlings are pricked out 4 inches apart; keep them in the stove till they have again taken hold of the soil, giving them a little shading meanwhile, some tissue paper does very well. Remove them to the warmer part of the greenhouse to be gradually hardened, so that they may be placed in cold frames by the 1st of June. By the middle of July they ought to be large sturdy plants ready for 5 and 6-inch pots, which I think best for almost all purposes of decoration.

I prefer the shallow boxes for several reasons. First, the soil is more easily kept in a uniform moist condition, which is a nice point in *Primula* culture, and one not easily attained when they are grown in pots; also in transferring them to these large pots you get the balls of roots whole, and being confined in small compass they are cut in squares with a knife. The result of this treatment is the multiplication of roots, the same as the famous Clovenford process for treating young Vines; and the slight check received is more than compensated for by the extra number of roots produced to take to the new soil. If the plants in the boxes are watered before potting them, and the soil is in proper condition as to moisture, the frames being kept closed for a week and shaded, they should not need any water for that time at any rate; and this is of great advantage in insuring a good start. If the pots have been unused for some time they must be soaked in water for half an hour, taken out and left to drain before being used. The plants must have plenty of room in the frames, sufficient space being allowed between them for the free circulation.

It is advisable to pot the plants firmly, for they have very fine roots and are easily affected by drought if the soil is loose. Pot them well down in the soil, as this prevents large plants twisting about. Of course the flower stems must be picked off as soon as they can be seen throughout the growing season.—JOHN SWAN, *Kilmalcolm, Renfrewshire.*

### RHODODENDRON FORMOSUM—HYBRIDS.

SEVERAL handsome *Rhododendrons* are grown in conservatories now, and either planted out or in pots and tubs they are much appreciated ornaments for such structures. The Himalayan species are the most beautiful as regards the size and individual importance of the flowers, but unfortunately they are mostly rather unsatisfactory in habit. They are apt to produce long straggling branches bearing heads of flowers at their extremities and with the lower portions bare of foliage. This tells more against their employment than anything else; but happily there are some other species of *Rhododendrons* suited for the same structure, but possessing a compactness of habit combined with a floriferousness that renders them very useful. One of these is *R. formosum*, by no means a novelty, yet not common even now. In a few large conservatories like that in the Regent's Park Botanic Garden and in the Winter Garden at Kew, good examples may be seen that, when bearing their pure white flowers freely in April or May, have a charming effect. The late J. H. Mangles was an admirer of this plant, and from his well-grown collection the flowers and shoot engraved (fig. 15), were sent some time ago. It is a good form of the species, as the flowers are sometimes smaller and less expanded than shown in the cut. It requires a good, free, peaty compost, with plenty of sand and thorough drainage when grown in pots.

*R. formosum* has been employed by several hybridisers in crossing with other species, and Mr. J. Anderson Henry, who paid much attention to the matter, related some interesting particulars concerning this and allied *Rhododendrons* in the *Journal of the Royal Horticultural Society* (1873) which may be repeated here. After noting some peculiarities in the hybridising of *Veronicas*, he proceeds as follows:—

"I have no doubt something of the same kind occurs among *Rhododendrons*. But I may only instance one case where I crossed *R. Edgworthii* on *R. caucasicum*; the seedlings, ever few when the cross is a severe one (by which term I mean such instances as where the species do not affect

each other kindly), were only two in number; and though now about ten years old, they show no indications of setting for flower. But while they have both the glabrous foliage of the seed-bearer, and even the ochreous tint underneath, they differ in having pyriform instead of its lanceolate leaves. But though in these particulars they depart from the normal state of *R. caucasicum*, they have not one feature of *R. Edgworthii*, the male parent. The other case is where I crossed the same *R. Edgworthii* on *R. Jenkinsii*. Here the seedlings, again only two in number, resembled the mother, except in having again the pyriform foliage, in which, be it observed, it is a departure from both parents, both having lanceolate leaves, those of *R. Jenkinsii* being acutely so. The hybrid in this latter case is huddled for flower; but the flowers of both parents are white, and both sweet-scented, and among the largest of the genus, though the scent, texture, and forms of the flowers are different; so that I look for surer tests in the coming flowers, though these may be more perplexing too than any that yet appears. It is proper to observe that I take the utmost precaution in all my crossing operations to prevent miscarriage in any possible way.

"While treating of my difficulties with this *R. Edgworthii*, one of the most peculiarly constituted as it is one of the most peculiarly featured of all the *Rhododendron* tribe, having its rugose leaves densely pubescent on the upper while it is perfectly shaggy with tomentum on the under side, every stem being clothed with the same tomentum, I have another most

"vocabulary of abuse." I cannot allow even "*D., Deal,*" to employ a phrase, attribute its authorship to another, and found thereon a charge of something more than discourtesy against me, however worthy his object may have been in doing so. I have heard "*D., Deal,*" described as a "facetious man," and I have no objection to his indulging in a little fun at my expense in a reasonable way. More anon.—A THINKER.

#### BOWOOD MUSCAT GRAPE.

I WAS much interested in Mr. Thomson's remarks respecting this Grape (page 48), as it refreshed my recollection of the pen and ink war he refers to, which I well remember, and as the Editor invites the opinion of other experienced readers I for one have pleasure in relating mine. When I took charge of these gardens I found a house recently planted with Vines, and among several others were Muscat of Alexandria and Bowood Muscat. The latter I had then no knowledge of, but for a good reason it soon became a favourite of mine by its being a frequent first prizewinner. These Vines, which are now things of the past, were early forced every year, and I never could succeed in getting a perfectly set bunch of Muscats except from Bowood, which is one of its always superior qualities. This is not certainly its only distinctive feature. As compared with Muscat of Alexandria, the latter is long both in bunch and berry; whereas the Bowood bunches are shorter, heavily shouldered, and the berries more egg-shaped than Pear-shaped. In regard to colour, and flavour the two are equal, but the primary difference is the free-setting quality of Bowood. I have no doubt the cause of so many believing in the identity of the two sorts is that the true variety is little known. I have, like Mr. Thomson, bought what had been called Bowood, but not true.

I observe, among other remarks of Mr. Thomson's, he considers Gros Marcc very inferior in all respects to Gros Colman except in colour, which I thoroughly agree with, and would further say that in my opinion it is the worst flavoured Grape I know, and should never be awarded a prize except for colour. Gros Colman, when ripened thoroughly black, which can only be accomplished by a long season and plenty of heat, is in my opinion the best late Grape we have, though I admit it cannot be kept good so long as Lady Downe's, and I shall be much mistaken if in a few years Gros Colman will have become one of the most extensively grown Grapes in cultivation.—RICHARD WESTCOTT, *Raby Gardens*.

As you invite the opinion of experienced men as to the identity or otherwise of the above-named Vine with the Muscat of Alexandria I gladly offer the following.

I well remember the Bowood Muscat Grape being figured in the "*Florist*," and as I was at that time about to plant a vinery with the object of having late Grapes, I wished to give the preference in greater part to Muscats. I felt interested in getting variety if such was to be

obtained, and acted upon that idea. About the same time, too, the late Mr. Pontey of Plymouth gave an account of a Muscat growing in the gardens at Tehidy Park in Cornwall, which he named Muscat Passique as being distinct and well worthy of recognition. His description was asculogistic as that of the Bowood which was then so prominently before the public.

I had a friend who volunteered to get for me the Tehidy variety. I had access also to a good old Vine of the Muscat of Alexandria, so I carefully reared plants of the two above named, and the Bowood I obtained direct from the late Mr. Turner of Slough. Now, as he was a gentleman of the highest honour, and, moreover, associated with Mr. Spencer of Bowood as joint editor of the "*Florist*," it seems impossible to suppose I could have had the Bowood from a better source. The three varieties so called were planted side by side, and have grown so to this day without my ever being able to detect the slightest difference.

Many of the readers of the *Journal* will doubtless remember a fruit catalogue issued antecedent to the above date, and compiled by Mr. Thompson of the Royal Horticultural Society's Gardens, which was a very reliable guide to fruits of all kinds, and in it a prominent feature was that all the best known, whether among Apples, Peaches, Vines, or any other fruits were shown to have many aliases or synonyms, and I apprehend the good old Muscat of Alexandria was as well worthy as any to be thus represented; hence, a sufficient reason if the fruit tree succeeded in a better manner than ordinary either by culture or situation, men were induced to believe in all sincerity that they had a superior variety, and a name to distinguish it from others was given to it. In that way I think a *bona fides* was given to mark its excellence, and those who accepted this theory were assured that a really good thing was secured to them, and from which they could not possibly suffer disappointment.—J. ENSTONE.

#### FERNS.

I HAVE read the whole of Mr. Newsbam's lecture on Ferns published in your columns, and I consider that some of the statements it contains

Fig. 15.—*Rhododendron formosum*.

singular peculiarity to note in regard to it—namely, that while it will cross other species, it will take on a cross from none,—that is to say, while it has been repeatedly made the male, it has never with me, though I have tried it often, nor with any other that I have heard of, submitted to become the female parent. I have crossed it repeatedly on *R. ciliatum*, one of the minor forms, too, of Dr. Hooker's Himalayan species. It has been crossed, too, on *R. formosum* in this neighbourhood, I believe, in the Stanwell Nursery; but I could never get it to take on any cross whatever. *R. Nuttallii* behaved with me in the same manner; it would cross, but not be crossed; but I did not persevere with it as I did with *R. Edgworthii*. Now I do not assert absolutely that *R. Edgworthii*, in the numerous tribe of which it is a member, may not be hybridised with some other of its kindred, but I could never get it to reciprocate a cross. And this remarkable circumstance of non-reciprocity has perplexed and defied me in innumerable instances throughout my long experience in these pursuits. It occurred to me that the pollen of larger forms might be of larger grains, and so might not pass through the necessarily small ducts of the styles of smaller species: yet *R. ciliatum*, a tiny species of 1 foot high, was crossed freely by *R. Edgworthii*, as I have just noticed, a species of 6 feet high. I even crossed this latter species on a pure Indian *Azalea*, though, by pulling the seed-pod before it was ripe, I raised no seeds of this latter cross."

An extensive progeny was also obtained by crossing *R. Nuttallii* with a hybrid obtained from *R. formosum* and *R. Dalhousianum*, amongst which were some seedlings of great merit.

"*D., Deal,*" AND O'CONNELL.—Permit me to say, in answer to a curious paragraph on page 27, that I will show in an early issue that "*D., Deal,*" is entirely inaccurate in his quotation from O'Connell, and that the term "individual" cannot be legitimately included in the

are of a misleading nature. The first error I would refer to is that *Lastrea dilatata* is said to be known as the common Male Fern. The common Male Fern is the *Lastrea Filix-mas*, and *L. dilatata* is the Broad Buckler Fern. The next part of Mr. Newsham's paper I will call attention to is as follows:—"Of the forty-eight British Ferns we have twenty-one rock Ferns, twenty-one which inhabit rich soils, six marsh Ferns." Now, I infer from the above that Mr. Newsham intended his hearers to understand that we have forty-eight distinct species of British Ferns. But the whole of the pteridologists are against him, for forty-three to forty-five are all that are accepted by any one of the writers on the subject. The following is a list of the species that are accepted as such by all who are considered authorities on the subject:—*Adiantum Capillus-Veneris*, 1; *Allosorus*, 1; *Asplenium*, 9; *Athyrium*, 1; *Blechnum*, 1; *Botrychium*, 1; *Ceterach*, 1; *Cystopteris*, 3; *Gymnogramma*, 1; *Hymenophyllum*, 2; *Lastrea*, 8; *Osmunda*, 1; *Ophioglossum*, 1; *Polystichum*, 3; *Polypodium*, 4; *Trichomanes*, 1; *Scolopendrium*, 1; *Pteris*, 1; *Woodsia*, 2; in all 43; and I believe in no more that are worth the rank of species.

The next part of the lecture in question is his reference to liquid manure. The following are his own words:—"Liquid manure I rarely use. I look upon it as teetotallers look upon beer. It may be, in fact I believe it is, useful when given to a plant which is sickly; but even then it must be very weak. If the Ferns thrive well, let well alone." I wonder what a teetotaller would say to a doctor recommending beer to a sick patient and at the same time condemning the use of it by those in good health. I feel certain that such advice is not from experience. But I have reason to believe that healthy plants are benefited by occasional supplies of liquid manure, but I should withhold it from any plant in a sickly state.—A CONSTANT READER.

### WINTER DIGGING.

As this is an important matter with most gardeners, and as opinions differ as to the best methods of ameliorating the soil, I beg to suggest a method which I have not seen advocated in your columns, but which has proved very beneficial. Some years ago I took charge of a garden at the commencement of the new year; my predecessor had got the work up so far close by having had nearly all the vacant ground dug. The weather had been very wet; the soil was a strong clay. One of the labourers said, "That ground is ruined for two or three years, but he (my predecessor) would have it dug let the weather be what it would," and suggested that what vacant ground there was I should have ridged like Mr. ——— had them done years ago. Observing that he was a good workman and of good common sense I allowed him to lead and do it as he thought best. "I suppose 2 feet 6 inches apart will do; that will do for Peas and 'Taters both, also for Cauliflowers." "Just so," said I, "do the best you can." He commenced by marking off the ground (being careful to see that it ranged with the adjoining quarters 2 feet 6 inches apart; then taking the soil from alternate spaces and laying it on the solid soil similar to taking out the soil for a Celery trench, the moved soil, by being laid above the surface, was fully exposed to the action of the weather, and when the time came for planting the exposed soil was found to be very friable. The trenches were refilled, drills drawn, and Potatoes planted, the spaces between forked over, thus leaving all the ground in good condition. For Peas the same method was adopted with Spinach between, but prior to filling in the trenches a heavy coating of manure was put in and the soil filled in. For strong soils this is the best method I have ever practised, if not necessary in all places.—J. GADD.

### THE PERCIVAL COLLECTION OF ORCHIDS.

THE large and renowned collection of Orchids formed by the late R. P. Percival, Esq., Cleveland, Birkdale, Southport, have been entrusted to the Liverpool Horticultural Company for sale. Some idea of the extent of the collection may be formed when it is stated that the plants numbered over 4000, and comprised according to the catalogue 1352 lots. This was much the largest collection of these plants in that part of the country, and was on view from January 25th to Tuesday, February 2nd, when the sale of the plants actually commenced. It would not be known until the following day or two who really became the owners of some of the most important plants that the collection contained, for although all the plants were priced it was provided that in case more orders than one arrived for each plant they would be placed on one side on the morning of the 2nd inst., and after informing the buyers, not present, by telegram, would be sold by auction the following day.

On Wednesday, January 27th, a large company was invited to inspect the collection, and numbers of gentlemen and gardeners were present from various parts of the country. An excellent lunch was provided, at which probably 150 or more persons were present, including amongst others Mr. G. Bethel, gardener to the Duke of Marlborough, Blenheim; Mr. E. Cooper, gardener to the Right Hon. Jos. Chamberlain, Highbury, Birmingham; Mr. Swan, gardener to E. G. Wrigley, Esq., Howick House, Preston; Mr. Hathaway, gardener to the Earl of Latham, Latham House, Ormskirk; Mr. W. Moss, gardener to W. Holland, Esq., Mossley Hill; Mr. Glover, gardener to Sir A. B. Walker, Bart., The Grange, Woolton; Mr. W. Mease, gardener to C. W. Newmann, Esq., Wyncote, Allerton; and Mr. Bostock, gardener to Enoch Harvey, Esq., Riversdale, Aigburth. The toast to Orchid growers and gardeners was suitably responded to by Messrs. Swan, Cooper, Glover, and Mr. R. G. Waterman, gardener to A. Tate, Esq. The two former Orchid growers both highly

complimented Mr. Beddoes, who had grown this excellent collection for the late Mr. Percival, on the healthy condition of the plants generally. It is indeed difficult in a large collection to maintain every plant in the highest state of health, for both had found from experience that plants were very much like individuals, and some out of a large number were sure to be on the sick list. It was clear from the remarks of these two able cultivators that they attributed much of the success that had been attained with this collection to starting with fresh healthy plants. Mr. Swan strongly advised beginners, in fact all who desired to have plants in a satisfactory state of health, to commence with strong healthy pieces. Their remarks fully bore out what has appeared in these pages that large established plants are liable to go back, at least for a time, when they pass into other hands.

Mr. Swan raised the question of pruning and syringing for discussion. It is clear that the advocates of the former amongst Orchid growers are exceptions. Judging from what was said on this subject further pruning than the removal of spent pseudo-bulbs—that is, after they commenced shrivelling, were not believed in. Much discussion was raised on syringing, and there were present strong advocates of both systems. Mr. Cooper strongly condemned the syringing of *Phalaenopsis*, and stated that when this practice was adopted he could not keep them in good condition through the winter, but had succeeded admirably since he discontinued it. Mr. Cooper being an advocate of low temperatures preferred the plants to have moisture naturally deposited upon them in the morning. Mr. T. Moss advocated a free use of the syringe daily, and found that only beneficial results follow, provided care be taken to evaporate the moisture from the axils of the leaves and growths before evening. He also devised other means to attain this end, even if a piece of sponge were used for the purpose; but this is too laborious an operation, and could not commend itself where large numbers of plants are grown. Mr. Swan's remarks on this subject were general, believing, as he does, in a judicious use of the syringe, fully taking into consideration the weather, position and construction of the house in which the plants are grown, as well as other varying circumstances that the grower has to contend against. Liquid manure for Orchids was another topic raised by some whose names I failed to obtain. It was generally agreed that liquid was beneficial for terrestrial Orchids, but for epiphytes it was not wise to use it farther than to stand it about the house to be evaporated in the atmosphere. It may be mentioned that the collection that had been under Mr. Beddoes's charge had enjoyed a judicious use of the syringe, and no one could fail to admire their clean healthy condition.

To return to a brief notice of some of the leading plants in this collection which filled four of the largest houses in the Vineyard. The plants were arranged under numbers, and with the aid of the catalogue were easily found and examined. The *Cœlogynis* were wonderfully healthy, and the plants of *C. cristata* varied in price from 5 to 20 guineas. Some of the pans in which the plants were growing were 33 inches in diameter, and contained no less than 320 pseudo-bulbs. A plant of *C. Lemoniana* (Trentham variety) in a 30-inch pan, remarkably fine, with 210 large pseudo-bulbs, and over 3 feet in diameter, was priced at 25 guineas. The variety makes an enormous difference in the price; for instance, two other specimens, probably 6 inches more in diameter, were offered for 8 guineas each. A very healthy plant of *C. Massangeana* with five leads was on view for 20 guineas; *C. Lowii*, two leads, one flower spike, 5 guineas.

*Laelia anceps* and its varieties were very numerous with quantities of flowers, but the house was not suitable for their opening. Some of these plants were really splendid, being most luxuriant in growth; as an example, one plant with thirty-seven pseudo-bulbs and eight flower spikes may be mentioned. The growth was fully double the strength this variety is usually seen. Some idea can be formed when I state that the leaves were 3 inches wide and proportionately long. The plants of this variety, thirty-seven or thirty-eight in number, varied in price from 10s. 6d. to 12 guineas, while a plant of *L. anceps Percivaliana*, with ninety pseudo-bulbs and twenty-four flower spikes, was 100 guineas. Another plant, with thirty-nine pseudo-bulbs and eight spikes, 40 guineas. The next was a large plant of *L. anceps* mixed with *Percivaliana*, 20 guineas. *L. Percivaliana delicata* (this is the whole stock of this variety), twenty-eight pseudo-bulbs, three flower spikes, 20 guineas. Plants of *L. Hilli*, with three and four flower spikes, 10 guineas each. *L. Dawsoni*, twelve pseudo-bulbs and one spike, 17 guineas. Smaller plants, with three, six, and seven pseudo-bulbs, 3, 5, and 15 guineas each. A small plant in a 5-inch pot of *L. D. alba* (Bull's variety), with eight small pseudo-bulbs, 10 guineas. A plant of *L. anceps Barkeri*, with fifty-eight pseudo-bulbs and fourteen spikes, said to be a fine variety, 30 guineas; and five smaller plants, varying from 5 to 10 guineas. There was a good stock of semi-established plants of *L. a. nivalis*, varying in price from 10s. 6d. to 58 guineas.

*Cypripediums* were not numerous, but all were in robust condition, and some of the plants remarkably large and well flowered. *C. villosum* (Rollinson's variety), with fourteen flowers, 10 guineas. Another plant, with fifty-six flowers good variety, very fine, 12 guineas. *C. superbiens* (Prince Demidoff's variety) was remarkably good, having ten growths, price 10 guineas. There was also a grand plant of *C. insignis punctatum violaceum*, with twenty growths, 20 guineas. Smaller plants at 5 and 10 guineas each. *C. insignis Maulei*, very strong, twelve growths, 5 guineas. A plant of *C. Dominianum*, fifteen growths, 10 guineas. There were also fair plants of *C. caudatum*, 10 guineas. *C. Sedeni*, with twenty-three growths, the same price. *C. selligerum*, fifteen growths, 8 guineas. *C. Spicerianum*, with seventeen growths, 10 guineas. There were several plants of this variety all wonderful for their luxuriant growth.

*C. lævigatum*, twenty-two growths, 8 guineas. The plants of *C. concolor*, *C. ciliolare*, and *Lawrenceanum* were all small, but remarkable for health. There were seven plants of *Cypripedium eburneum* with from five to sixteen leads, and were quoted at from 3 to 10 guineas each. *Ada aurantiaca* was a magnificent plant with twenty-nine leads, 5 guineas. The old *Zygopetalum Mackayi* was represented by plants with ninety-six bulbs and twenty-four leads bearing as many as seventeen flower spikes, price 5 guineas.

Cattleyas were the principal feature of this collection, and *C. Mossæ* was represented by no less than sixty-five lots in the catalogue, varying from magnificent masses on rafts, with 280 pseudo-bulbs, showing thirty-eight flower sheaths, and priced 20 guineas, to small plants 2s. 6d. to 5s. each, but the majority amounted to guineas each. Noticeable was a fine plant of *C. M. Arnoldiana*, with seventy bulbs and ten sheaths, at 20 guineas. *Cattleya Percivaliana* was represented by a large number of plants in the best condition. One large plant on a raft, with 170 pseudo-bulbs and sixty fully developed flowers, was very beautiful. 100 guineas was required for this plant; 75 guineas for another with thirty-five flowers on a raft, 20 guineas for another with nine flowers, 50 guineas for another with thirty-six bulbs and six flowers, this being the plant that produced the flowers figured in the "Orchid Album." There were also two plants of the white form of the above at 15 guineas each, one having ten bulbs and two sheaths, and the other one sheath and ten pseudo-bulbs. *C. Skinneri* was very well represented, the largest plant with 316 pseudo-bulbs, 30 guineas, was not in the best of condition. Another, 25 guineas, with 140 pseudo-bulbs. *C. S. oculata*, a plant with the same number of pseudo-bulbs as the last, 40 guineas. A plant of *C. Mendeli*, with 158 pseudo-bulbs and twenty flower sheaths; another with forty-four pseudo-bulbs, five flowers, good variety; a third, with seventy-seven pseudo-bulbs and eleven flowers; a fourth, with seventy-two pseudo-bulbs and ten flowers, were priced 50, 25, 20, and 20 guineas respectively in the order named. *C. Mendelii aurea*, with eighteen pseudo-bulbs, 10 guineas. The flowers of this plant were figured in the "Orchid Album." Another superior variety, twenty-eight pseudo-bulbs, 15 guineas. *C. labiata* (autumn-flowering variety), with twenty pseudo-bulbs, 20 guineas. Three other plants, two with seven pseudo-bulbs each and one with eight, were 12, 10, and 7 guineas in the order named. A fine variety of *C. exoniensis*, with two leads, 25 guineas, and a small but very healthy plant of *C. Brymerianum*, with twelve pseudo-bulbs, two small leads, 25 guineas. *C. Mossæ Hardyana*, two leads, 15 guineas. *C. Sanderiana*, 140 pseudo-bulbs, forty-two leaves, marked A1 variety, 30 guineas. The highest price for *C. gigas* being 10 guineas, and the same for *C. Gaskelliana*. *Lælia elegans alba*, forty-eight pseudo-bulbs, three flower sheaths, four leads, 50 guineas. Other plants, with four and five leads, 25 guineas each, the first being marked A1 variety. *L. Schilleriana*, six leads, 15 guineas. *C. Trianae* was represented by a number of plants. A specimen named *formosa*, with sixty-two pseudo-bulbs and seven flower sheaths, 20 guineas. Another plant, with forty-five pseudo-bulbs, 15 guineas. *C. T. Osmani*, thirty-six pseudo-bulbs, three sheaths, 20 guineas. The same price being required for *C. T. Normani*. Amongst *Dendrobiums* the highest prices were 10 guineas each for *D. Schroederi*, *D. clavatum*, *D. densiflorum*, *D. Jamesianum*, *D. fimbriatum oculatum*; *D. Wardianum*, 8 guineas; *D. snavissimum*, *D. chrysotoxum* at the same amount; and *D. Ainsworthi roseum*, 10 guineas; *Lycaste Skinneri alba*, with one lead, three fine flowers, 15 guineas. Another plant, with two leads and the same number of flowers, the same amount. *Oncidium macranthum*, 8 guineas.

To attempt to enumerate all the leading prices of the principal plants this collection contained would take up too much of your space. Prices very similar to what have been given were quoted for plants of other species and varieties of Orchids that I have not attempted to name, and I do not doubt that when the whole of the plants have been disposed of many of the prices given will be considerably exceeded. There appeared to be no lack of Orchid enthusiasts after the rare and valuable varieties which this collection contained. It would indeed be very difficult to estimate the number of Orchids in the Garston Vineyard at the present time, for quantities of houses are full of semi-established plants, others newly potted up, besides thousands of newly imported in every shed and corner likely to suit them until they are disposed of. Two or three other large importations are daily expected, and it may truly be said there are Orchids everywhere, and those who have not seen the enormous quantity of plants on previous occasions would naturally wonder when the whole would ever be disposed of.

This is only one branch of horticulture carried on by the Company, for Roses, Vines, and decorative plants of every description are grown by thousands to meet the demands of their cut-flower and plant trade.—WM. BARDNEY.

#### USEFUL WINTER VEGETABLES.

THE past was undoubtedly a very dry summer, and has caused many bare places both in market and private gardens, consequently green vegetables are very expensive. In some counties these can scarcely be obtained at any price, in Berkshire and Oxfordshire notably. Those who made good provision by growing plenty of Seakale will fully realise its usefulness in a spring like the present is likely to be. I have before written in these columns of its value. Where it has been properly cared for the whole stock was taken up in November, except where a quantity is required through April and early May, then one row is taken out and two left; but I think almost as good a way is to clear the whole plot and lay in the crowns in a late corner in the soil yard or in the garden, and

cover with litter before it begins to grow. If it is allowed to grow before covered it will not come a good colour. I have found cocoa-nut fibre refuse very useful for covering it, as also is bog mould where at hand. Seakale is seldom refused at table, and it may be bad from the end of November until the following May.

Another vegetable I much esteem is the old-fashioned green called Ragged Jack. A provision may always be made for a few rows of this hardy useful vegetable. I have never seen this destroyed by frost; in fact, I never had a failure with it, even when the garden has been bare of other green vegetables or nearly so. In a dry season I sow seed in drills the same way that I should sow Turnips, except that the rows for the greens are 18 inches apart. I have found Lapland Kale do well grown the same way, and they will amply repay for a little trouble in shading or netting to protect them from birds. Spinach Beet should be in every garden of however small pretensions. It is useful at all seasons. Swede Turnips should have the leaves twisted off instead of being cut off, leaving the crown intact, as the young growths produced when the Turnips are placed in a dark shed are often used when Seakale is not plentiful. I consider this makes a very useful dish, much better than what is often seen in gardens under the name of Seakale.—J. P.

#### WINTERING POT STRAWBERRIES.

MR. CHALLIS remarks in the third paragraph of his interesting paper (page 61) on this subject, that while the method of plunging the pots in an upright position either in leaves or ashes effectually overcomes the evil of undue exposure of the roots, it is still open to serious objection; and in support of this assertion he says "that in very dry positions or in dry winters no harm may ensue, but in damp situations or in wet winters this often leads to most disastrous results by the plants being kept in a constantly wet and sodden state during the period of rest, when comparative dryness should be their condition(?)." I beg to point out to Mr. Challis that there is no necessity for Strawberry plants plunged to the rim of the pots in ashes in an upright position becoming sodden at the roots during wet winters, seeing that the site selected for that purpose can and should be higher than the ground surrounding it, in order to prevent the possibility of water settling there. Such a situation is the best possible winter quarters. We have wintered about 3000 Strawberries in this way annually for the last fourteen or fifteen years with perfectly satisfactory results. In the event of severe frosts we cover the plants lightly with dry fern at night, which—the plants occupying a sunny aspect—is removed the following morning as soon as the influence of the sun has rendered such a course practicable. The evil of the plants becoming blanched in consequence of the covering being left too long over them is certainly very great, but is nevertheless more imaginary than real in practice, though undoubtedly if the protecting material were allowed to remain unnecessarily long on the plants the latter would become somewhat blanched and impaired in consequence.

I should like to know upon what grounds Mr. Challis arrives at the somewhat strange conclusion that the condition of Strawberry plants in pots which are laid on their sides during the winter and early spring months, is "more nearly like that to which they are naturally accustomed." We all know as a fact that the Strawberry plant in its natural state in gardens, and that, too, during the resting period, when Mr. Challis says it should be comparatively dry, receives direct from the clouds three times the amount of water at the roots that it does at any other time, thus plainly proving that the Strawberry is not only perfectly hardy when "comparatively dry," but also when perfectly wet. The conditions under which the Strawberry plant naturally flourishes out of doors are not quite in harmony with the ideas advocated by your correspondent.—W. S.

I READ with much pleasure, at page 61, Mr. Challis's excellent remarks, and I assure him the plan is exactly the same as that practised by my lamented old master, George MacEwan, at Arundel, who used to grow Strawberries with great success. It is also the plan I have followed for at least thirty years; in fact, it is the only practical one.—R. GILBERT.

#### FARMERS AND GARDENERS.

I THANK "Thinker" for his kindly remarks on my small contribution to the discussion at present going on in the pages of the Journal on the above subject. With nearly all that "Thinker" says I agree, and when I say this, my points of divergence from "Utilitarian" will be plain enough, and need not be stated here.

I may, however, remark in regard to one of "Thinker's" sentences, that he has somewhat misunderstood me when he asserts that I seem to imply that our old country will be "bowled out of existence" by the competition of other lands. I never thought so, and never meant anything I wrote to be understood as meaning so. I could not help taking notice of what is only too apparent—viz, that foreign competition is on the increase, and will go on increasing as years roll on. I endeavoured to make plain that such competition must be met on our side by certain measures which I named, and added that though "some may go to the wall in the struggle . . . that the majority will be able to 'rub along' . . . so that a due reward may be found attending the labours of those who, having found many things against them, resolutely set themselves to overcome all difficulties." That is not the language of one who fears that our country will be "bowled out of existence."

Then, in regard to horticulture, I remark that "horticulture generally . . . seems passing through a trying time, but let us again hope that the

result of all its trials may be an increased hold on the people," &c. This again is not the language of one who thinks his country is on its "last legs." There is so much that can be said on such matters as the "gentleman market gardener" who sells from necessity, the same individual who sells from choice; the market gardener who has to complain of unjust rating; the distressed farmer who has to complain of hard bargains and harder landlords; the equally distressed farmer who has in a great degree only his own want of skill and enterprise to blame for his want of success; the generous landlords who have given all encouragement and aid to their tenants that they were able to afford; the landlords who from rent reductions and unlet lands are unable to draw enough from their estates to pay the mortgages and encumbrances on them, and who have the unsatisfactory and unhappy position of the appearance of wealth without the reality." All these might engage our attention in the Journal, as certainly they demand our attention in the carrying on of the affairs of our country.

How best to meet and mitigate all the various difficulties and hardships attending these several great departments in our national economy should engage the thoughts of all who wish that in spite of everything Britain may still retain her supremacy, and her sons be able to cultivate her soil in the future with such a measure of success as will enable them to live in comfort and happiness. There can be no doubt that we are on the eve of great changes in regard to the land question; let us hope that these changes may be so carried out that every encouragement will be given to those cultivators who are anxious and willing to cultivate the land in a thorough and liberal style, giving to it freely so that they may receive as freely.

This should be encouraged in every way, and such arrangements should be made as would offer every inducement to cultivators to keep their land up to the highest pitch in regard to fertility by the assurance that when they gave it up at any time they would receive a due recompense for having cultivated highly to the end of their occupation.

It is not necessary that I should repeat my ideas in regard to the equal rating of market gardeners pure and simple and gentlemen marketers. I differ from "Utilitarian," and hope that in due time something will be done to place matters on another footing. Regarding "Utilitarian's" remarks about the need of a higher education for farmers and gardeners—he especially mentions the latter, but I think both need it—I may say that much might be done in that direction by many of both classes with very little expense and not much trouble, comparatively speaking. Gardening periodicals are now plentiful and cheap, books on gardening abound, opportunities of seeing other places are easily within reach of the mass of young gardeners, and if there is the will to improve there is little to prevent anyone from attaining to much knowledge which at present often lies hid, simply from want of will and the exercise of study, which would suffice to improve matters greatly if indulged in. As long as many gardeners fail to recognise that they are following a most elaborate and complicated profession, which requires a varied set of attainments if it is to be thoroughly pursued and successfully engaged in, then there will always be such "gardeners" as "Utilitarian" refers to.

In like manner, until farmers come as a body to recognise that farming is capable with profit of being made a science, we shall have men attempting to farm who are utterly devoid of much that is necessary to continued success in farming, and wonder will continue to be expressed that they do not succeed. Then, again, many farmers have at the present time not been able to bring themselves down to the times; they cannot think to deny themselves many things that they could at least want till on a better footing again. But they must ever bear in mind those virgin lands which "Thinker" seems to think I make too much of, also the ever-increasing facilities of transit, and the fact also that their brethren beyond the seas, one in most cases managing to get along by dint of hard work, and the denial of many little luxuries that our distressed agriculturists think they could not dispense with. No one wishes that they should be deprived of these when they can pay their way and face all competition with success, but as long as "distress" is the cry, increased efforts must be combined with increased economy. We must bear ever in mind that the landed interest, the farming interest, and the horticultural interest, cannot be independent of one another; the prosperity of the one means the prosperity of the other, they all hang together, and all who wish success to any one of them, must also wish well for the others.

We must look for wise legislation in the immediate future, we must hope for better times as regards our climate, we must encourage every effort in the way of individual enterprise, and we must weigh all our difficulties and competitions aright, and show our old British pluck by rising superior to them all.

May the difficulties we have to encounter only stimulate us to increased efforts, so that the future will disclose a time of material prosperity which will enable that branch of the fine arts we call horticulture to flourish as freely and generally as any reader of the Journal could desire. —J. T. S.

#### MILDEW.

In reply to the query propounded by "J. L. B.," page 45, with reference to gypsum as a preventive of mildew, I may say that after a dozen years' experience I am fully convinced that it requires both the constituents of that article to effect a cure, not as gypsum, however, but by themselves, with the addition of soft water as follows—Take at the rate of 5 lbs. of flowers of sulphur to 4 lbs. freshly slaked lime, add one quart of water to the pound, boil slowly half an hour, stirring all the while. Allow it to settle, then strain through a thin cloth, and when cold bottle and cork tightly. It will keep for months, and is always

ready for use. For Roses I generally use one bottle to two ordinary large watering pots of rain water, and apply it in the evening, syringing well with clear water early the next morning. Under glass it is better to use a weak solution; for late Peas it is required stronger, and so on, but that is a matter easily determined by the exigencies of the case. It is scarcely necessary to add that it ought to be applied at the first indications of the disease.—H. C. W.

THE NATIONAL AURICULA AND CARNATION SOCIETIES' schedules are now to hand, and announce that the exhibitions for the present year will be held respectively on April 20th and July 27th in the conservatory of the Royal Horticultural Society's Gardens, South Kensington. It is stated that by the terms of the schedule "the Auricula exhibition is for one day only, but it is hoped that many exhibitors will allow their plants to remain during the next day as the integral parts of the great exhibition of Primulaceous plants that will probably prove a bright feature of the next London season." The accounts of both Societies show a small balance, and with a larger accession of members they will be soon placed in a fairly prosperous condition.

— AMONGST the objects of interest at the forthcoming Colonial and Indian Exhibition will be a rare collection of indigenous AUSTRALIAN GRASSES. The specimens are named to correspond with the nomenclature used in the "Flora Australiensis," and there is in addition much practical information about each, derived from general sources.

— THE annual meeting of the NURSERY AND SEED TRADE ASSOCIATION was held on the 25th of January at 25, Old Jewry, E.C. The chair was taken by Mr. Sherwood (of the firm Messrs. Hurst & Sons Houndsditch), and the ninth annual report was read and adopted. It was stated that there had been a proposal to wind up the Association in 1884, but several energetic members being convinced of its usefulness in affording reliable information respecting the stability of persons in trade that could not be otherwise obtained, had assisted in strengthening it, and the result was a favourable balance of over £48. Several toasts were proposed and responded to by Messrs. Sherwood, H. H. Clarke, Harrison of Leicester, William Paul, Hooper, C. Butcher, and Harry J. Veitch, and the meeting altogether proved very satisfactory.

— MESSRS. BARR & SON, King Street, Covent Garden, send us a pan of GALANTHUS ELWESI, which they state "has been out all the winter till the last few days, when put in a cold frame to protect the blossoms from the dashing rain. It was intended for the Floral Committee, but as it does not meet till the 9th inst., I fear the flowers may be past." They were beautiful, healthy examples of this fine Snowdrop, the outer divisions of the perianth being pure white and nearly seven-eighths of an inch in diameter. We have never seen better specimens. We gave a good illustration of G. Elwesi in this Journal March 19th, 1885, p. 227.

— A CORRESPONDENT remarks that in the note on page 65 of last week's issue "the imports of wine into France last year are said to have been over 180,000 gallons. Ought not this to read 180,000,000 gallons?" A reference to the context shows that the latter amount is the correct one.

— WE have to record the death of MR. JOHN SCOTT of MERRIOTT, SOMERSETSHIRE, which occurred on the 22nd ult. He had paid particular attention to pomology, and formed very extensive collections of fruit trees and Conifers in his nursery. He was in his 79th year at the time of his death, and was much respected in the district.

— AT the Meetings and Shows of the ROYAL HORTICULTURAL SOCIETY in the present year Messrs. James Carter & Co., High Holborn, London, will offer the following prizes on the dates named:—May 25th, Cucumbers, three prizes; June 22nd, Melons and Cucumbers, three prizes each. July 13th, for Peas, four prizes. July 27th, for Beans, Lettuces, and Cabbages, three prizes each. Sept. 7th, for Tomatoes, three. Oct. 12th, Onions, three; Cauliflowers, three; and Runner Beans, three prizes each; and on October 26th, Potatoes, four prizes.

— A YOUNG GARDENER writes as follows respecting sowing EARLY PEAS:—"At this season of the year there is much said about sowing Peas in pots and boxes for planting out, while there is a good old method scarcely ever mentioned. It is as follows: Cut some turf about 1 foot long, 4 inches wide, and about 3 inches deep. Afterwards cut a channel in the turf  $1\frac{1}{2}$  inch deep and 2 inches wide, in which to sow the Peas. The turf can then be placed on a Vine border or any other suitable place, and the Peas sown and covered. When the Peas have grown sufficiently to require hardening or planting out they can be removed to the desired place without disturbing the roots, as is the case when sown in pots or boxes."

— THE PORTSMOUTH CHRYSANTHEMUM SOCIETY appears to be in a flourishing state, and its Committee animated with a spirit of enterprise. According to the balance sheet, the first show, that of last year, left a profit of £42 4s. 4d., and an incentive for popular support is provided in the offer of a silver cup value £25 and £5 on the first prize; 70s. for the second, 50s. for the third, and 20s. for the fourth prizes, in a class of thirty-six blooms, half Japanese and half incurved, accorded to the usual conditions stated in the schedule. The Show will be held on November 11th and 12th. Mr. F. Power, 26, Queen Street, Portsea, is the Honorary Secretary.

— INSECTS AND FRUIT TREE CANKER.—The members of the Astwood Bank Amateur Gardeners' Society had under consideration at their last meeting letters which have recently appeared in the gardening press relative to Mr. James Hiam's theory of insects causing canker in fruit trees. Mr. Hiam, enforcing his contention, stated that the mites to which he traced the injury were so small that "it would take at least 40,000 to cover a square inch of surface of bark or wood." The Committee thought it advisable to postpone further consideration for a future meeting.

— AS an example of how LATE DISPLAYS OF CHRYSANTHEMUMS may be had, Mr. H. Lister, gardener to Lord Brooke, Easton Lodge, Dunmow, Essex, sends us a collection of blooms cut from plants that were raised from cuttings struck in July. All were extremely fresh, bright, and most valuable at this time of year. The varieties are Lady Selborne, Madame C. Audiguier, Albert, Beauty, and Comtesse de Beauregarde from July cuttings. The others, grown in the ordinary way, are Grandiflorum, Fanny Bouchardat, Bronze Dragon, and Boule d'Or, giving a good diversity of colours and blooms of convenient size for cutting.

— MR. R. OWEN, Maidenhead, also sends some BLOOMS OF CHRYSANTHEMUMS Nuit d'Automne, Belle Paule, Mrs. Mahood, and Boule de Neige, all very fine, and remarks, "I send you these to show how long they are lasting in flower this season. Besides those sent I have Fair Maid of Guernsey, Ethel, Sarnia, Colibri, Meg Merilees, &c. Last week I cut some splendid blooms of M. Henri Jacotot, a rather early Japanese variety. The blooms sent are from plants grown as ordinary bush plants for decoration and cutting purposes."

— PRESERVING TIFFANY.—A correspondent, "D," asks if any of our readers can tell him how to make tiffany decay-proof otherwise than by boiled oil. This latter process does not answer, as the tiffany gets torn by the wind, being very brittle when oiled. He wants the tiffany to remain soft and flexible.

— WAKEFIELD PAXTON SOCIETY.—The subject for discussion by the members of this Society on Saturday last by being popular and simple was none the less interesting, "Mignonette for Pot Culture," being the title of Mr. R. Hall's paper. Mr. Hall, a well-known gardener in Sheffield, treated his subject so well that the favour in which this sweet-scented flower is generally held was considerably increased before the close of the meeting, as a great amount of information not generally known was elucidated both in the essay and the discussion which followed. The thanks of the members were heartily accorded to Mr. Hall for his essay.

— A GARDENER of great experience writes:—"I have read with unbounded pleasure 'A. L. G.'s' remarks on the ANALYSIS OF SOIL. This makes us gardeners put on the studying cap; in fact, it tells us what few of us know, and I feel sure that I speak the sentiments of the great majority of your readers when I thank him heartily. If 'A. L. G.' will oblige me with his address I should esteem it a great favour." It would perhaps be well for our correspondent to indicate any further information he may need, and we have no doubt "A. L. G."

will supply it through the Journal, when others will share in the benefit of his teaching.

— GARDENING APPOINTMENT.—Mr. S. Taylor, late of Acacia and Malsis Hall Gardens, Yorkshire, has been appointed gardener to Arthur Hodgson, Esq., Clopton House, Stratford-on-Avon.

— "A. M. B." writes:—"I am greatly obliged by 'A. M.'s' friendly and most useful suggestion as to PLANTS FOR HERBACEOUS BORDER, and interested in the mention of *Trillium grandiflorum*, as I was just about to query whether *Trillium erythrocarpum* (figured on page 50 of 'Juliana Horatio Ewing and Her Books'), described as a North American plant, had been found to succeed under English cultivation. On Tuesday, the 27th January, showed the snow gone except here and there. The air was clear; the sunshine bright. The 28th dull and gloomy, very cold. Dull, rain, and cold to-day (29th). At 1 o'clock snowed heavily, continues to snow, and inclined to thaw."

— ACCORDING to the report for the past year of the Superintendent of the ROYAL BOTANIC GARDEN AT CALCUTTA, further attempts to introduce into Bengal the kind of Plantain (*Musa textilis*) from which Manila hemp is derived have proved failures owing to the low temperature of the cold weather; but the plant (*Sansevieria zeylanica*) from which bow-string hemp is obtained grows very well. The Japan Paper Mulberry, which has lately been introduced, has also been a success. Efforts are being made to introduce other plants of economic value, the principal being the Coca plant, from which the important alkaloid cocaine is derived. The additions to the herbarium during the year appear to have been unusually large and comprehensive. As an example of the public utility of the Garden, it may be mentioned that 20,433 living plants were distributed to public institutions in India, while those sent abroad were proportionally numerous. In the same way 2979 packets of seeds were sent out. The report of the Lloyd Botanic Garden in Darjeeling is also included in the paper, which concludes with the usual statistical returns.

— THE PAXTON SOCIETY, HUDDERSFIELD, decided some short time since to vary the fortnightly meetings with papers read by gentlemen who are known to excel in some particular branch of horticulture, and to invite gardeners, amateurs, and lovers of flowers to attend. The first of these meetings was held on Jan. 30th, and proved very successful. Upwards of sixty members and friends were present. The President, G. W. Rhodes, Esq., presided. Mr. W. Swan of Howick House, Preston, kindly gave an essay on the native habitats and culture of Orchids. The essayist described most minutely the various genera, districts, temperature, and altitude in which Orchids are found; also the heavy rainfall and extreme heat the various sorts are exposed to, concluding by advising low span-roofed houses as best for all the sections, varying according to the size of the plants. Ventilating, shading, and potting materials were also fully described; in fact, the paper was quite exhaustive and very interesting. A hearty vote of thanks to the above gentleman and Chairman brought a very pleasant evening to a close. The next paper to be read, on February 13th, is by Mr. C. Smedley—subject, the "Amaryllis." The Huddersfield Chrysanthemum shows were inaugurated by the Paxton Society, and are under its management. We are glad to record these and similar instances of horticultural activity in various parts of the country; all gardeners and gardening improvement societies having our best wishes for their success.

— REFERRING to the EXPORT OF FRUIT FROM TASMANIA, a local paper says:—"We have seen Dr. Benjafield's men gathering and putting up 200 quarts of Hobart Strawberries for the Sydney market. The American screw-down bottles were brought on the ground in boxes which held from one to two dozen each, and through the middle of the box was a board with holes in it, so that each bottle fitted into one of these apertures. As these boxes were old packing cases, they cost but very little, and are very effective. Before filling each bottle is thoroughly fumigated with sulphur fumes, which was effected by a very simple contrivance. A flower saucer was filled with sulphur and lit, then the flower pot was turned over it. The fumes soon poured out of the hole in the top in abundance, and the open mouth of each bottle was stood over it for a few seconds until the bottle was full. Each picker now marched off to a bed with a box of these bottles, which, as they were filled with fruit, were put back into their holes, and the case, when filled, brought back to the light spring waggon, which took them to the boat. But before starting each bottle was surrounded with green stuff, Cabbage leaves, &c., to keep

it cool during the voyage. The fruit was gathered not quite ripe, very ripe or damaged fruit being rejected. They were the ordinary Trollope Strawberry, but Dr. Benjafield tells us there are firmer-fleshed Strawberries than these which will carry much better, plants of which he hopes to obtain. The British Queen is one of these, but here they are not yet ripe. As the last lot sent fetched 1s. 6d. per quart, he hopes these will fetch more, as they are riper and look better. At 1s. a quart clear a good acre will bring in from £250 to £300. If these experiments prove a success and the demand in Sydney is unlimited, we cannot see why a good thing should not be made of it; and if, as appears probable, Raspberries, Currants, Peaches, and all soft fruits can be thus carried much more easily than Strawberries, it in the future will be a splendid thing for our fruit-growers."

— THE Secretary of the Illinois State Horticultural Society makes known some strange facts in regard to the ORCHARDS OF ILLINOIS, UNITED STATES. In the northern and central parts of the State a large proportion of the Apple, Pear, Peach, and Cherry trees are dead or in a dying condition. Of Apple trees this proportion is one-half; of Pear trees it is 65 per cent.; of Peach nearly 90 per cent.; and of Cherry trees over 50 per cent. In the southern part of the State the case is not so bad, though even there nearly one-half of the Peach trees are dead or dying; 15 per cent. of the Apple trees, 18 per cent. of the Pears, and 27 per cent. of the Cherry trees are ruined. A large part of the remaining trees are also in an unsatisfactory condition. The varieties of Apples in the northern and central parts of the State that have stood the severe tests of the late winters are as follows:—Duchess of Oldenburg, Snow Red Astrachan, Willow Twig, Wealthy, Whitney No. 20, Yellow Bellflower, Tetofsky, Tallman Sweeting, Westfield Seek-no-further, Sops of Wine, Salome, Minkler, Maiden's Blush, Roman Stem, and Grimes' Golden; the last four being reported only for the central and not for the northern part of the State. These few hardy varieties will now be in demand for future planting. It would now be interesting to know to what extent shelter belts have been employed for orchards in Illinois, and precisely what protection they have afforded the trees.

— AN Orchid grower writes:—"Many fail to successfully cultivate ONCIDIUM TIGRINUM, especially when it is placed at the warmest end of the Odontoglossum house. In this position it is generally kept too moist during the winter, or that period of the year when it should receive a season of complete rest. If watered during the dreary days of winter on the same principle as Odontoglossums, it frequently decreases in size until it finally succumbs. From the time its deliciously fragrant flowers are produced this Oncidium should be kept dry at its roots; in fact, no more water should be given it than sufficient to prevent its large fleshy pseudo-bulbs from shrivelling. If this is done it will rest in the moist atmosphere of the Odontoglossum house, and will grow with vigour, increasing in size and strength annually. This variety is worth every care and attention, as it flowers during winter, and in colour is totally distinct from Odontoglossums flowering at that period, and therefore very effective when arranged amongst them."

— AN American paper announces the institution of the MISSOURI BOTANICAL GARDENS as follows:—"The eminently public-spirited citizen of St. Louis, Mr. Henry Shaw, who proposes to give his celebrated Gardens to the city on his decease for the enjoyment and instruction of the people for ever, has not waited for the event of his departure to inaugurate his generous gift. He has already founded a school of botany, endowing it with real estate which even now produces an income of over 5000 dollars a year. Prof. Wm. Trelease, an eminent botanist among the younger class of men, has been placed in charge, and inaugurated on the 6th of November. It has been made a department of Washington University. The whole movement so far seems to indicate a bright future, and must be highly gratifying to Mr. Shaw, the generous promoter of the measure. The Engelmann Herbarium and other famous material will, it is hoped, go to the charge of this new department of the University."

— THE same paper states that the formation of a BOTANICAL GARDEN AT MONTREAL has been under discussion since 1863. Since Prof. Penhallow has been Professor of Botany in the University the project has taken shape and seems now entirely successful. It embraces 77 acres; the arboretum takes of this 40 acres, 5 acres will go for aquatics and similar plants. The plant houses are to cover 216 feet by 90. There will also be lecture rooms, library, and an economic museum. The city furnishes the ground, leases it to the Gard. Associa-

tion, and the citizens find the money. The Horticultural Society is its chief supporter. The Dominion Government, however, appropriated 1,000,000 dollars to put the garden in a good preliminary condition. The prospects at present indicate that this garden will be one of the most successful in America.

### NOTES ON GRAPES.

THE Journal lately has been very rich in excellent advice and hints from noted Grape-growers, and I should like to jot down a few remarks suggested after reading these notes on Grapes. In conversation recently with a gentleman who, while not professing to be a Grape-grower, is very much interested in the subject, and is at the same time a very shrewd, practical, and scientific farmer, I gave it as my firm conviction that all Grapes do not need the same food, which he questioned, but correctly observed that some might require more than others. Before proceeding farther I would ask in the case of the splendid Muscats at Longleat, why should not the Alicantes, or rather the Blacks, be equally good in berry? In the exhibits at South Kensington I first noted the great difference in the size of the berry, and then when I saw them at home I noted the difference still more. Of course the bunches were very large, but undoubtedly there was a want of size in the berries of the black varieties. Now, presuming these were treated in the same manner in feeding, what should cause the difference? In other cultural details there might be a little variation, such as in the amount of heat, water, and ventilation; yet the black varieties, being healthy and in good condition, I conclude that the Muscats had all they required, and the Alicantes did not. Lady Downe's were very good. Mr. Taylor at Bath cannot fail to note the superiority of his Gros Colman and Alicante both in berry and finish to his Muscat, all grown in the same house, and I believe Vines of the same age. How is this? Amongst my own Vines perhaps the only one that gives me satisfaction is the Gros Colman; this stands any amount of feeding, with the result that the berries are large, and when only fairly cropped are of good colour. Alicante, on the other hand, disappoints me. Certainly the colour is good, but greater size of berries is wanted. Mr. Taylor's Alicantes had decidedly the best berries of any I saw last year, though the bunches were not large. Lady Downe's pleases me in the berries, but not in the bunch.

Comparing the three varieties of Grapes I have named, how do they stand for keeping, which after all is the test of good growth? First for sound noble appearance is the Gros Colman. Then there is but little to choose between Alicante and Lady Downe's. I prefer Alicante now; the only fault—and on this hangs a tale—is the stoning. In Lady Downe's I can pick out plenty of berries with five stones, this can readily be told by the markings on the berries. The great objection I find to this variety is that unless the berries are stoned they will shrivel and decay rapidly. Alicante is very deficient in stoning, and this, too, received the same treatment as Lady Downe's. I now come to the conclusion that Alicante must have extra food, more so, I believe, than the others named, but whether it is to take the same form I cannot say. The chief reason for not giving extra food to Alicante is the great strength of the laterals and the large foliage. I should be afraid of using potash for fear of not ripening the wood, as I use but little fire.

Stoning is entirely under the influence of the grower, as I have proved. The Madresfield Court berries have as many as six stones, where in the same Vine the year before they were very deficient, and this result is obtained by liming and root-feeding. Lime is an all-important factor, being so simple that its value is either ignored or doubted. In large borders the absence of lime is quickly discovered. In small or confined spaces it is not so soon found out, because I suspect the latter are better looked after perhaps both in water and feeding. Liquid manure and other modes of feeding delay the discovery of want of lime. I can point out one very narrow border, in fact a Cucumber bed, now used for Alicante and Lady Downe's, which I know is deficient of lime; yet this season, with extra attention in other ways, the Vines produced the largest berries I ever saw, and at the same time some of the smallest berries. What appears to be wanted in Vines generally is a good feeding of lime in spring or summer as required, and then, probably to make doubly sure, apply it again in the autumn. In my own experience I have had borders naturally full of lime, and in this case of course supplied other food.

In conclusion, I have not the slightest doubt that it is the best grown Grape that keeps the best, and to grow it to perfection very close observation and application are required. In making Vine borders, provided the mechanical condition is right, all that the Vine needs can be given as required. The simpler the compost—in fact I used no manure—the better for the well-doing of the Vine. —STEPHEN CASTLE, *West Lynn*.

### WARSCIEWICZELLA VELATA.

MOST of the Zygopetalums are generally cultivated even where Orchid collections are small, and some of them, such as *Z. Mackayi*, are much appreciated for their useful free-flowering habit. Very closely allied to them, but not nearly so well known, are the Warscewiczellas, of which a few species have been described and introduced, but by some authorities they have been all referred to the genus Zygopetalum. There are several other genera also that have occasioned much discussion, of which *Bollea*, *Huntleya*, and *Pescatorea* may be named as examples, but as certain minor distinctions have been observed in them they are, with the exception of *Huntleya*, given separate rank now.

The Warscewiczellas are natives of Central America, but though from tropical regions they are more frequently injured by excessive heat than by any other cause, unless it be undue dryness. Like most Orchids that have no pseudo-bulbs, they do not need such a strongly marked season of rest as those which have stores of nutriment to support them, consequently a moderate supply of water is required at all times. In other respects they may be treated the same as *Zygopetalums*, growing them in pots in a compost of good peat and sphagnum moss, with adequate drainage to prevent any approach to stagnation. This is the simple treatment adopted by such experienced Orchid growers as Mr. B. S. Williams, and it has been found very successful. One of the best of the species is *W. velata*, represented in the woodcut (fig. 16) prepared from a sketch of a handsome well-grown plant at the Orchid Conference last year. It produces its flowers abundantly, clustering amongst the leaves or scarcely rising above them; sepals and petals white or tinged with yellow, the lip similar in the ground colour, but streaked and stained with purplish crimson, lighter in the throat. Though not so showy as some other Orchids it is pretty, and the flowers have a very agreeable fragrance. *Warscewiczella aromatica*, with white and purple highly fragrant flowers, is another useful species; *W. Wailesiana* creamy white with a purplish lip, *W. Wendlandi* white blotched with purple in the lip, and *W. candida*, white, are other species that are worthy of a place in large collections of Orchids.

#### GARDENING IN CALIFORNIA.

THE following extracts from a letter just received from "the Golden State" may perhaps interest some of your numerous readers in this

Fig. 16.—WARSCEWICZELLA VELATA.

country. They are written by a friend who is head gardener to a gentleman there.—W. H. DIVERS, *Ketton Hall*.

"We had a very dry summer. For five months there was not a drop of rain, and hot winds were blowing every day. We had to water all plants with a hose, as we could not keep them moist enough, and we are now (Jan. 6th) getting very bright days and frosty nights. We have not a good thermometer outside, but I should judge the frost lately to have been from 7° to 10°. In the wet season it does not rain—it pours—not for a few hours, but for days, and sometimes a week, without stopping. Before the rain comes everything not irrigated is parched up. After a few days' rain the fields and roadsides suddenly turn green again.

"Gardeners are not kept to look at here. We have to work hard, and have great difficulties to contend with. A gardener does not hold the position here that he does at home, and masters as a rule do not treat their servants well. The general style is, 'How much do I owe you? Here's your money. I do not require your services any longer.' — is gardener in a small place near here; he gets about £13 per month, and his board extra for looking after the house during absence of the family. Everything here is very expensive, especially clothes. Doctors charge £1 per visit. Meat is the only thing that is cheaper than at home.

"I see by the papers things are very unsettled at home. 'England is fast becoming a democratic country. They talk of the freedom of this country. I have not seen much of it yet, and on the whole a working man is better in England if he only gets a living. That is all he does here; but there is one advantage here—he can buy a plot of land, build a house, and have a home of his own; but a man is better off in England on half the money.

If you hear anyone speak of coming to this country advise them not to come. Hundreds, I might say thousands, are seeking work."

#### DEATH OF MR. JOHN ROBSON:

It is with much regret that we have to record the death of one of the oldest contributors to these pages—Mr. John Robson, who was for many years gardener to the late Earl of Cornwallis and Viscountess Holmesdale at Linton Park, Maidstone. Mr. Robson was established at Linton Park when he was placed on the staff of the *Cottage Gardener* in 1851, and was an indefatigable contributor to its pages and the *Journal of Horticulture* till 1875, when he relinquished his charge at Linton, a substantial pension being granted to him by Lady Holmesdale in consideration of his long and faithful services, but this pension ceased at her ladyship's death. On Mr. Robson's health somewhat improving he resumed his pen, and until within a comparatively recent period sent an occasional article for insertion. He was a regular contributor during a period of thirty years, and no sounder articles on practical gardening have been published than those in which he recorded his experience. He was thoroughly competent as well as most genial and obliging, one of his greatest pleasures being to assist all who needed advice on gardening matters. On this it will be fitting for those to speak who knew him best.

An opportunity was afforded in 1876, for the termination of Mr. Robson's labours at Linton Park was felt to be an appropriate time to recognise the merits of one who had done so much for gardening both by his work and pen. A committee was therefore formed and steps taken to carry out the project of a testimonial, and the labours

of that committee closed in a pleasant manner on the evening of the 29th October in that year in the village inn at Linton. At a social meal there spread J. Philpott, Esq., as a principal promoter, presided, and after making a brief address vacated the chair in favour of J. Neve, Esq. (who was for many years Steward at Linton), and who was deputed to ask Mr. Robson's acceptance of the offerings of his friends. After duly honouring the toast of the Queen, Mr. Neve uncovered a handsome silver inkstand, and a purse containing £126, with a list of 160 subscribers, and presented them to Mr. Robson. In doing this Mr. Neve remarked that after having had close business connections with Mr. Robson for many years he desired to bear public testimony to his worth and ability. Not only as a gardener, but as an accountant and assistant Mr. Robson had rendered him invaluable aid, while his character for integrity, industry, and urbanity had won him the approbation of all around him. Mr. Neve dwelt with emphasis on the generosity of Mr. Robson's disposition in ever seeking to impart knowledge and in being constantly ready to render assistance to all needing a helping hand, and his matured judgment had been of the greatest benefit, not only to the district, but also, through the press, to the general community.

Mr. Robson's acceptance of the gift well represented his character as a thoughtful generous-minded man.

When the applause had subsided, Mr. Robson, in the midst of an ovation almost overwhelming, in a modest speech and tremulous accents, accepted this one more mark of recognition which had been kindly rendered to him for "trying to do his duty." When he first became acquainted with the object of the committee his first desire was to stop

any further proceedings, but on further consideration he thought it would not be right to others for him to do so; therefore as an encouragement to others to labour for a reward, and also as his acceptance of the gifts of his friends might possibly enable him to better help some others who might be afflicted as he had been, he received with sincere thanks the kindness of those who had considered him worthy of their notice and regard.

On the inkstand was the inscription—"Presented to John Robson by his neighbours and friends as a token of their regard and esteem.—Linton, October 1st, 1876."

The Secretary of the fund spoke of the many flattering letters he had received in regard to Mr. Robson; Mr. Bradley, Preston Hall, and Mr. Goddard, Hunton Court, alluded to his well-proved friendship to them and to all gardeners to whom he could be of service; and the representative of the *Journal of Horticulture* acknowledged the valuable aid rendered by Mr. Robson to horticultural literature for a period extending over a quarter of a century.

Mr. Robson had already been the recipient of a gold watch and chain for his services in connection with the Maidstone Gardeners' Society, and he was held in the greatest esteem by all classes in the neighbourhood in which he so long resided. He was born at Lamesley, Gateshead, on March 25th, 1812, and died at Hunton, near Maidstone, February 1st, 1886.

### GROS COLMAN VINE.

WHILE the topic on Gros Colman Vine is yet fresh, I thought I should like to relate a circumstance which I witnessed two or three seasons ago. Thrips appeared in a viney in which Gros Colman was planted with Lady Downe's, Mrs. Pince, Alicante, and Black Hamburg. In order to check the ravages of this pest the usual remedy was applied—viz., fumigating with tobacco paper. The house was filled with smoke in the evening as the sun was going down. The next morning Gros Colman presented symptoms of distress, the edges of the leaves were curled up, and looked far from being right, while the other Vines were as fresh and healthy as ever. As the day wore on and the sun shone on the house matters became worse. The leaves of the Vine of Gros Colman appeared as though they were scorched. Shade was put on, but it did no good. Many of the leaves were cut off as useless. Perhaps some of your able correspondents can tell us something more of this matter. I may add this Vine border received large supplies of liquid manure.—FAIRPLAY.

I HAVE read with interest the remarks in your columns respecting the treatment of Gros Colman Vine, and I will briefly describe my experience. Two years last spring I planted a house with Gros Colman. I found that when they had made shoots from 6 inches to 1 foot long they began to be scorched, and without exception had to make new leads. I then had recourse to shading by laying on linseed oil with which a very small portion of white lead had been mixed. The following spring they were affected in a similar manner, although the frosted glass afforded a certain amount of shade. In the autumn of the same year I had some holes made in the front wall to allow of the roots passing outside, as they were planted inside in narrow border. I then made an outside border. At one end was a washtub for catching roof water, which I also utilised for liquid manure, principally made from fowls' manure. Last winter this tub frequently overflowed with heavy rains. As a consequence that end of the border received an extra share of moisture. The fertilising properties of the manure it contained had a very marked effect on the two nearest Vines. They grew away from the first without scorching, have made such canes as are not seen every day, and have ripened splendidly; the other Vines all had to make second shoots as usual. My experience leads me to think that Gros Colman requires an extra amount of moisture, also plenty of liquid manure. Although I should not recommend shading to be dispensed with, at least till the Vines have got strong hold of the border, I have no doubt a little extra attention, as giving air early and warming the pipes, would repay the grower. Gros Colman seems to exude moisture more than any Vine I know. I have generally gone over them every morning two or three times with a stick to knock off the wet. I have found in my general practice that potash is a most useful ingredient for Vines, having used it very extensively for several years, but I have not used any in this instance, not being able to procure it very readily here. I have no doubt it would prove useful to even Gros Colmans.—R. SOWERBY, JUN.

### THE STAGES IN PLANT HOUSES.

WITH the new season no doubt there are many who intend to erect new glass houses, so that my remarks may be worth a place in our instructive Journal. Some houses have been erected here lately, one of them being a plant house (lean-to), having a stage in front and against the back wall. Under the front stage four rows of 4-inch pipes run the entire length of the house, the stage being an open wooden one and about 1 foot above the pipes. Consequently the plants are very difficult to manage, as the heat coming up between the open boards dries them so quickly that the labour in keeping them moist enough is very great. For Calceolarias, Cinerarias, and many other plants such a stage is ruinous, when the heat has to be maintained to keep out sharp frost as we have had to do lately. Under such conditions plants cannot be made very satisfactory, for they lose their strength and grow weakly and sickly, and many are useless. If instead of an open wooden stage a stage of blue slate had been made, resting on an iron frame, the legs of the frame

on the pavement edge, as I have seen elsewhere, the dry heat from the hot-water pipes would be prevented from coming direct to the plants and would be a great gain to them as well as to the gardener. The temperature would be more equal, they would grow strongly, and give entire satisfaction if other points were attended to.

Houses are sometimes erected without the gardener being consulted in the matter, which I think is a mistake, for as a rule gardeners are intelligent men and their opinions are often valuable. I would commend those intending to build plant houses to form stages, if of open wood-work, well elevated above the pipes. In doing this it will be necessary to carry up the wall to the proper height.—C. J.

### GARDENERS' CHRYSANTHEMUMS.

IN the many articles which appear on Chrysanthemums, their merits for exhibition either for prizes at a show or for home display in the greenhouse are almost always strictly kept in view. For many country gardens exhibition culture is a delusion and does not pay, and many of the sorts which are necessary to the producers of large flowers are worthless to those who want and must have a good supply of flowers. We like to have a good supply of Chrysanthemums from October to February. About the middle of the former month they, as a rule, begin to be very useful, and up to the beginning of February we can always find good use for them. We have had them as late as May, but they were grown more in the way of showing what can be done than for any particular use. Large blooms are by no means despised, as for some purposes they are valuable, just as large double Dahlias and Richardias are appreciated, but as a rule medium-sized flowers are best. Varieties of the Mrs. Rundle class are simply invaluable when compared with those of which Queen of England is the type. The culture of the Chrysanthemum is in all respects so simple that it is of no importance to enlarge on it here. The main points to be observed are these: To choose short strong root cuttings, to grow them cool in all cases, to pot firmly, and rather under-pot than err on the side of having too large pots; abundance of water is also necessary, and good feeding is of much importance. In June the taller varieties are cut down to the moderately hardened wood. Dwarf sorts are not cut down. The grower for usefulness does not require to disbud his plants in the orthodox manner. Should he do so he will reap a harvest of disappointment. A beautiful shaded old variety, General Bainbridge, gave me the first lesson as to how Chrysanthemums should be grown to yield abundant flowers. This variety had been disbudded and produced its three flowers to each stem, but while these were passing through their several stages of development and final decay, several growths were made down the main stems, each of which produced a neat little flower. After that we did not trouble much about disbudding varieties which were inclined to be prolific of stem flowers.

Of course the varieties grown are of the greatest importance in securing the end in view—plenty of flowers, and a long-continued period of usefulness. The number of sorts grown must be strictly limited, and a larger or smaller number of each sort cultivated in order to meet the demand. The varieties we grow in greatest number are Madame Desgrange, the plants of which are so managed as to yield a supply for the first five or six weeks of the season. G. Wermig and La Vierge will in future be grown to come in with this kind. Of Mrs. Cullingford we shall also grow a few plants. The best of the main group are Mrs. G. Rundle, Mrs. Dixon, and Mr. G. Glenny. When left to grow naturally the main centre flower on each shoot has two smaller buds close to it, which open at the same time, while we have often had a dozen good side blooms from each upper growth. The plants require very good treatment in order to bring these to a fair size. James Salter and Lady Selborne are also favourites, the latter coming in quite as early as the Rundles, and lasting till Christmas or later. Each stem of these produces four good blooms, or twelve to one main growth, besides smaller blooms, which are produced later. Others of the main group is the variety just named—General Bainbridge. This is not only a free-blooming variety, but the colour of the flower is very taking with ladies, and, indeed, for home use it is most valuable. *Jardia des Plantes*, though not floriferous, is of such a beautiful yellow tint that it is indispensable. *Beauté du Nord* is very good, as also are *La Nympe*, *Hiver Fleuri*, *Tokio*, *Insigne*, *Elaine* (the best in cultivation). *Gluck* is a fine yellow Anemone, *Princess Louise* very taking, *Say Mayant* (?) a good late form. Of *Anemone Pompons*, *Autonius*, *Madame Montels*, *Cedo Nulli* and its yellow variety, and *Calliope* are all useful. Ordinary Pompons are not of any value. Good late varieties include the old *Julie Lagravère*, *Fair Maid of Guernsey*, *Rex Rubrorum*, a very good sort, *Madame C. Carey*. With exception of the last named these are flowering freely just now; the other is later. We have also *Mons. Astorg* very good at present. *Peter the Great* is sometimes fine, but not always. *Fulgore*, *Diamond*, and *J. Delaux* are grown for colour of flower. *Cullingfordii* has been disappointing, and so has *Salteri*, but better things may follow another season.

A little heat works wonders in bringing on a batch of Chrysanthemums up to time; indeed we find fire heat of great value in the case of late varieties, increasing as it does the number of flowers which open. It may be added that we have no dislike to other Chrysanthemums, and, in fact, grow a large collection, but the above named we grow in quantities to meet a demand, just as we do *Miss Jolliffe* *Carnation* and certain *Geraniums* for this season.

Since penning the above an opportunity has occurred of inspecting a market growers' collection, and the results of a simple and cheap method of culture were so patent and satisfactory that an extra paragraph may be devoted to describing the treatment. The structure is an extremely

light home-made one of the cheapest character consistent with strength. The plants were all growing in the natural soil—apparently a poor sand. There had been no disbudding of the plants, but the removal of each central bloom as it was ready relieved the plant so far as to allow the side buds the full benefit of the foraging capacities of the roots. Many of these side blooms were in the third week of January 5 and 6 inches across, with the florets broad and leathery in texture. The blooms have brought wholesale to customers from the beginning of the season right on till now a uniform price of 3s. per dozen; to non-customers for odd orders a higher price has been charged. The chief sorts grown are Lady Selborne, Elaine, Lady Margaret, and in future years the Rundle varieties and Belle Blonde (?), a late incurved sort, is to be grown in numbers.

The system of producing the plants is most simple. A portion of one of the low heated frames was set apart in which a bed of soil is placed, and there we found cuttings dibbled in like *Calceolarias*, and there they remain until they are of good size, when they are lifted and potted. At the time for housing they are turned out of the pots and planted in the border of the house, where they open their flowers. To fill the place of the *Chrysanthemums* during the summer months thousands of seedling Tomatoes are coming on in a stove pit. These are to be grown as single-stemmed upright cordons, a system which we found several years ago to be a very good one.—B.

### KEEPING APPLES.

I CAN fully corroborate all that "B." and "Thinker" have said about keeping Apples in heaps as well as in single layers. For want of room I have been obliged to adopt that mode of storing them, and have found them keep well with very little attention; of course they were all carefully hand-picked.

I should like to say a word in praise of the Journal. It used to be a favourite of mine, but having for some years another paper found me, I had not seen it; now, having to find my own again, I have returned to the old love with pleasure and profit. I wish you much prosperity.—BUSHEY HOUSE.

### EMIGRATION TO QUEENSLAND.

IN answer to "A. B. C." I offer extracts from letters I received from a brother who emigrated last spring. He paid his own passage—but he should have accepted the assisted passage, it would have left him £10 more at the other end, and he had the same treatment as the assisted passengers. He was a journeyman gardener receiving 18s. per week, without lodgings. He is nineteen years of age, of spare wiry frame and dark complexion, a teetotaler and non-smoker—the very lad for a nearly tropical climate. I had one letter soon after landing, in which he says, "I have got work with a small farmer, wages 15s. per week and 'tucker,'—that is, 10 lbs. meat, 8 lbs. of flour, 1 lb. of sugar,  $\frac{1}{4}$  lb. of tea. My bedroom is an old shed, and my bed a few old sacks." And that is what one would have to bear from year's end to year's end. The recipe for damper is, "Mix up your flour and water, with a piece of baking powder, into a flat cake, put it in the ashes of your fire and cover it over; when you think it is done fish it out, give it a crack to knock the dust off, and it's ready to eat."

The second letter says, "I left my cockatoo farmer as soon as my time was up (it was a three-months engagement). Then I did a fortnight's work for a man where one of my shipmates is working; and now I have got work in the Botanic Gardens. I am to have £7 10s. a month to start, and £8 10s. if I suit. I live on the place; there are four employed besides the Curator. We start at seven in the morning and leave off at five in the afternoon, with an hour for breakfast and an hour for dinner, and leave off at one on Saturday. Every third week I stay in the gardens on Saturday and Sunday afternoons. Peaches, Grapes, and Oranges are plentiful. Germans are here in force; they use their Grapes for making wine. All the cockatoo farmers are Irish or German; there is not enough money to be made to suit an Englishman's constitution. Anyone who is fond of life had better not come here; it is very dull. A spree in Queensland is to go and sit in a "pub" and get drunk and remain so till all the money is spent, and then go and earn some more. I was lucky to get this job, as work is not over-plentiful just now, and one has to do what one can get, and not what one would like." From which I gather that a lad of sound constitution, abstemious habits, and one who is prepared to do work he would despise in England, will eventually get such wages that more money can be saved than he would earn at home. But for a married man who is earning a living in England, Queensland is no place to go unless an appointment is secured before starting.—A. L. G.

### THE PRIMULA CONFERENCE.

THE revised programme of this event is now issued, and though it has been previously referred to, we again notice it, as some alterations have been made. The exhibition will be held in the conservatory of the Royal Horticultural Society at South Kensington on April 20th and 21st in conjunction with the National Auricula Society's Show. The meeting for the reading of papers and discussion will be on Wednesday, April 21st.

PROVISIONAL PROGRAMME OF THE EXHIBITION.—Class 1, the Auricula; class 2, the Primrose and Polyanthus (special schedules for garden varieties in these two classes will be furnished by the National Auricula Society); class 3, varieties of *Primula Sieboldi*; class 4, varieties of *Primula sinensis*; class 5, European species, varieties and hybrids of

the genus *Primula*; class 6, Himalayan and other Asiatic varieties and hybrids of the genus *Primula*; class 7, Chinese and Japanese varieties and hybrids of the genus *Primula*; class 8, American, varieties and hybrids of the genus *Primula*; class 9, plants allied to the genus *Primula*, such as *Cyclamen*, *Dodecatheon*, *Androsace*, *Cortusa*, &c. (of these species only, not garden varieties, will be admitted); class 10, Primulaceous plants grown to illustrate special modes of culture, &c.; class 11, specimens, models, and drawings illustrative of the structure and mode of growth of Primulaceous plants.

PROVISIONAL PROGRAMME OF THE CONFERENCE.—1, "The Origin and History of the Florists' Auricula." Introductory paper by Mr. Shirley Hibberd. 2, "In what Direction should Efforts be Made with the View of Improving the Florists' Flowers belonging to the genus *Primula*?" Introductory paper by Samuel Barlow, Esq., J.P. 3, "The Nomenclature of Alpine Primulas." Introductory paper by Mr. J. G. Baker. 4, "Culture of Hardy Primulas." Introductory paper by Dr. Maxwell T. Masters on root structure, and mode of growth, as affording indications of the probable best culture.

APPENDIX.—In order to assist in the arrangement of the European Primulas at the Exhibition, Mr. J. G. Baker, F.R.S., has kindly drawn up for the Committee the following provisional list of European Primulas, classified in three groups, viz.:—1, Well-marked species distinguished from one another by broad clear characters; 2, Sub-species or varieties distinguished from the types under which they are placed by slight characters; 3, Probable hybrid types which have received names as if they were species.

The list may serve as a preliminary basis for the discussion at the Conference. Meanwhile the Committee suggest that exhibitors, in giving names to the plants which they exhibit, should follow, as far as they feel able to do so, the nomenclature and arrangement thus suggested by Mr. Baker. The names which are printed in italics are synonyms:—

Section 1, *Primulastrum*.—Young leaves revolute, not mealy beneath, calyx strongly ribbed. 1, *vulgaris*, Huds.; *grandiflora*, Lam.; *acaulis*, Jacq.—*Sibthorpii*, Reich.; *amæna*, Hort. 2, *elatior*, Jacq.—*Pallasii*, Lehm.—*Perreiniana*, Flugge.—*carpathica*, Fuss. 3, *officinalis*, Scop.; *veris*, Linn.—*macrocalyx*, Bunge.—*suaveolens*, Bert.—*Columnæ*, Ten. *Tommasin*, G. & G.

Section 2, *Aleuritia*.—Young leaves revolute, mealy beneath. Flowers small, with a long corolla-tube. 4, *farinosa*, Linn.—*scotica*, Hook.—*Warei*, Stein.—*stricta*, Hornem.—*frondosa*, Janka. 5, *longiflora*, All. 6, *sibirica*, Jacq.—*finmarchica*, Jacq.; *norvegica*, Retz.

Section 3, *Auriculastrum*.—Young leaves involute. Calyx short. 7, *Auricula*, Linn.—*Balbisii*, Lehm.—*ciliata*, Moretti.—*dolomitica*, Hort.—*Obristii*, Stein.—*similis*, Stein. 8, *Palinuri*, Petag. 9, *carniolica*, Jacq.; *integrifolia*, Scop.—*multiceps*, Frey.—*Freyeri*, Hoppe. 10, *marginata*, Curt.; *crenata*, Lam. 11, *viscosa*, Vill.—*pedemontana*, Thom.—*commutata*, Schott.—*latifolia*, Lap.—*graveolens*, Heget.—*ciliata*, Schrank.—*confinis*, Schott.—*villosa*, Wulf.—*hirsuta*, All.—*Berninae*, Kern. 12, *daonensis*, Leyb.—*oenensis*, Thom.—*Steliviana*, Vulp.—*cadinensis*, Hort.

Section 4, *Arthritica*.—Young leaves involute. Calyx long. 13, *calycina*, Duby.; *glaucescens*, Morett. 14, *spectabilis*, Tratt. *Polliniana*, Morett.—*Kitaibeliana*, Schott. 15, *Wulfeniana*, Schott.—*longibarda*, Hort. 16, *Clusiana*, Tausch.—*Churchillii*, Hort. 17, *integrifolia*, Linn.—*Candolleana*, Reich. 18, *Allioni*, Lois. 19, *tyrolensis*, Schott. 20, *minima*, Linn.—*serratifolia*, Gusm.—*Sauteri*, Schott. 21, *glutinosa*, Wulf.

Hybrids of section *Primulastrum*. *brevistyla*, D.C. *variabilis*, Goup. 1—3. *digenea*, Kerner, 1—2. *flagellicaulis*, Kerner, 1—3. *media*, Peterm.; *unicolor* Lange, 2—3. *Tenoriana*, Kern. 1—3.

Hybrids of sections *Auriculastrum* and *Arthritica*. *biflora*, Huter, 20—21. *alpina*, Schlecht.—*rhoetica*, Koch, 7—11. *Arctotis*, Kerner, 7—11. *Dinyana*, Lager, 17—11. *discolor*, Leyb. 7—12. *Dumoulini*, Stein, 20—14. *Facchini*, Schott, 20—14. *Floerkeana*, Schrad, 21—20. *Forsteri*, Stein, 20—11. *Gobellii*, Kern. 7—11. *Huteri*, Kern. 20—21. *intermedia*, *Portensehlag*, 20—16. *Kernerii*, *Gobel* & Stein, 7—11. *Muretiana*, Moritz, 17—11. *obovata*, Huter, 7—18. *Peyritschii*, Stein, 7—11. *Portae*, Huter, 7—12. *pubescens*, Jacq.—*rhoetica*, Gaud.—*helvetica*, Don, 7—11. *pumila*, Kern, 20—12. *salisburgensis*, Florké, 21—20. *Steinii*, Obrist, 20—11. *Sturii*, Schott, 20—11. *venusta*, Host, 7—9. *Venzoi*, Huter, 19—15. *Weldeniana*, Reich. 7—14.

### A COMPARISON OF MANURES FOR THE GARDEN AND ORCHARD.

[A paper by Professor G. C. Caldwell, Ithaca, New York, read before the Massachusetts Horticultural Society.]

How to manure the garden or the orchard for the most profitable results is one of the most difficult questions that the horticulturist has to meet. Of the biggest and most solid Cabbages, the earliest Peas, the largest Squashes, the sweetest and most prolific berries, the handsomest and most delicately flavoured Grapes, the most luscious Peaches or Pears, the earliest or the best late-keeping Apples, he has an unlimited variety offered him by all the seedsmen or nurserymen in the land; and he need find no difficulty whatever in laying out to good advantage all the money he has to spare for use in this direction. Of the most suitable land on which to plant all these crops there is enough and to spare somewhere in all this wide country. Of tools and labour-saving machines of every kind, and of men and animals to run or to use them, there is no scarcity. In respect to all these supplies there is only embarrassment of riches; and no crop need fail of producing good fruit abundantly, from any want of liberal provision for its highest requirements on any of these lines.

But is there such a superabundance of supply, when we come to the matter of the highest requirements as to the food for these crops? Is there a sufficiency of a supply of such kinds of food as will, in the general run of garden and fruit culture, give the surest results? Is not the gardener's call always for more stable manures? and is the call of the fruit grower any less loud? One naturally asks, Why is this so? when there are, elsewhere at least, immense if not inexhaustible quantities of the nitrogen, phosphoric acid, and potash, that are reckoned as so important plant nutrients, all to be had for the purchasing, and under so great competition that they ought to be had for as low rates as they can be sold for, paying fair profits. They can be had also in every form of combination, and every degree of assimilability, and in any desired mixture; and, further, to save the farmer or the gardener the trouble of studying out for himself the kind of combination that his crop needs, mixtures are offered to him, ready made up, for each crop.

Abundant as these supplies are, they do not seem fully to answer the purpose; for I doubt if the demand for animal manures is any less urgent now than it was before commercial manures became the important articles of trade that they now are. Yet, in agricultural operations, superphosphates, bone meal, nitrate of soda, and the like have, in some few cases, been made to take the place entirely of stable manure, with profit.

Perhaps you have heard the history of Mr. Prout's farm in England. Mr. Prout bought this farm in 1861; it comprised four hundred and fifty acres, and its cultivation in the manner to be described was, therefore, no small plot experiment. It was, when taken in hand, in a low condition of fertility; the owner asked the aid of the eminent agricultural chemist of England, the late Dr. Voelcker, as to the best way to bring the farm into good condition again. The advice was to dress it well with stable manure. After doing this with unsatisfactory results for two years application was again made to the chemist, who told the owner to use more stable manure; he said he could not afford it; then the chemist visited the farm again, examined it carefully, and suggested the use of commercial fertilisers after a certain plan. The plan was followed, and bone dust, superphosphate, dissolved guano, and nitrate of soda were the only manures used from that time on. The crops—clover, hay, grain, straw, and everything—were all sold standing; only an insignificant quantity of manure was made, the cultivation being almost entirely by steam. This system has now been carried on for more than twenty years. The estate cost the purchaser in the beginning, 74,500 dols.; enough more was spent upon it in improvements to make the total cost about 100,000 dols. The annual clear profits have been, on an average, about 4500 dols.; and it was estimated that the farm could be sold, eight years after it was taken, for twice what it had cost. Last fall the crops were reported as looking well, and the system was spoken of as continuing to succeed, although with the qualification that some fallows had been found necessary.

This is not the only instance on record of this kind of farming. Other cases have been reported where the system has been followed for forty years, in Germany. I give these few details in regard to this one instance merely to show what can be done with commercial manures when intelligently used—to show that they do contain all the food required by crops—and that, with their assistance only, a farm can be brought up from a low condition to a higher one, and held there for a series of years; and no one can show that what is true of farm crops should not be true of garden and fruit crops as well—if not to the same extent, yet to a large extent. They feed on the same kinds of soil, and in the same manner, and require the same nutrients in general; and the same particular nutrients that are specially important for farm crops are, so far as we know, specially important for garden and fruit crops; the proportions required may be different, but perhaps not more so than they are even for different farm crops; the same mixture of nitrogen compounds, phosphates, and potash salts will not answer equally well for Wheat and Potatoes, nor even for Wheat and for corn, which are more nearly alike than Wheat and Potatoes.

What are the obstacles in the way of the more extensive use of commercial fertilisers in the garden and fruit orchard, and of less dependence on the products of the city and village stables? In answering this question we naturally ask, first, what does stable manure contain that is not supplied in commercial fertilisers?

The valuation of a commercial fertiliser in the trade is based, as you know, on the quantities of nitrogen, phosphoric acid, and potash that it contains—some fertilisers containing only one of these nutrients, others two, and others all three of them. There is no question that in respect to just these nutrients we can meet the wants of any crop better by supplying commercial fertilisers than we can by stable manure, if there is any difference between the two as to efficiency. But, besides these, the crop must find in the soil, supplied from some source, lime, magnesia, sulphuric acid in the form of sulphates, of which plaster is one, a very little iron, possibly chlorides, of which common salt is one, and, perhaps, silica. Every superphosphate contains an abundance of lime and of sulphuric acid. The muriate of potash, brought from Germany, is a chloride, and contains chlorine. Of iron every soil has an abundance, many thousand times more than any crop needs; and the same is true of silica; of magnesia there is enough to be had in the German kainite. But as to all of these nutrients last mentioned—sulphate, chloride, silica, iron, and magnesia—there is no proof that the average soil is not abundantly rich in them for the production of good crops. Hence it is that we are justified in charging all the cost of a commercial manure to, and expecting to get our money back from, its nitrogen, phosphoric acid, and potash; the rest of the ingredients must be thrown in gratis, as of no value generally, although there may be cases where one or another of them may be of some service. All of these matters the stable manure also contains in abundance.

So far no one can claim anything for the stable manure that is not supplied by the commercial fertiliser. The only respect in which the two materials are distinctly unlike is this: the stable manure is composed largely of dead vegetable and animal matters in process of decay; the product of this decay is the humus or vegetable mould of the soil. About one-fifth of ordinary stable manure is made of this vegetable and animal matter, while not over six to eight thousandths is potash, five to six thousandths nitrogen, and three thousandths phosphoric acid. Of nitrate of soda, so much mentioned as a very useful fertiliser for its nitrogen, one-sixth is this nitrogen. Of a good superphosphate, as this fertiliser averages in this country, about one-eighth is phosphoric acid; and if one desires it,

and is willing to pay for it, he can have a superphosphate with one-third its weight of phosphoric acid; of a German muriate of potash from a third to a half may be potash. But in all these materials there is no vegetable matter, and little or no animal matter.

Here, then, is a clear distinction between the two kinds of manure, the stable and the artificial; the stable manure has its few thousandths of nitrogen, of phosphoric acid, and of potash, and its one-fifth of decaying vegetable and animal matter; the commercial manure only its few thousandths or even less of animal matter, and its proportions of nitrogen, phosphoric acid, and potash counted by eighths to thirds. About three-fourths of the stable manure is only water, however; expel this, and get a manure as dry as commercial manures ordinarily are, and the comparison between the two will be more just and no less striking; we shall then see that four-fifths of this dry manure is decaying vegetable and animal matter, about one-fourtieth is potash, one-eightieth phosphoric acid, and one-fiftieth nitrogen.

Can any way be now shown in which this striking difference between the two kinds of manure may account for the greater measure of success that is attained in general with the stable manure?

(To be continued.)

## PROPAGATING FICUS ELASTICA.

FOR usefulness and durability the Indiarubber Plant has become indispensable. Floral decorators and furnishers have long known the value of this plant with its bold foliage, which it retains even when subjected to long-continued hardships. It is rarely seen in a sickly state, whether it be in the window of the drawing-room, the greenhouse or conservatory, or the stove, and its requirements are so simple that anyone may succeed with it. Is it, then, to be wondered at that so many are desirous of possessing such an accommodating plant? When once purchased it is easily managed, and further, should it become dusty or dirty it may be cleaned in a few minutes.

It may be readily increased by means of cuttings, but when suitable cuttings are to be had the process is a very simple one. The two chief points to be secured are plump and prominent eyes and matured wood; if you have not these the chances are that the eyes will remain dormant for a considerable time. By way of verifying these statements I may turn to the fact that some years ago, before I was as well acquainted with the plant as now, I used to put in every piece that I could find, with the result that the soft immature wood seldom produced good plants; the cuttings would root in the usual way and remain for months without starting. These were ultimately thrown away, for the simple reason that they would not pay for room and attention. From this time I always endeavoured to insert only firm wood with prominent eyes, and I was invariably rewarded with a good batch of plants. The following is the method I now employ in the propagation of this plant.

Presuming a certain number of plants are destined for propagation, no matter whether they are plants with single stems or whether they are old stools and composed of several leads, I head them all back—in other words, take a good cutting of the leading shoot from each and, inserting them in single pots in sandy loam, plunge them in a bottom heat of 75° or thereabouts. This operation should be performed early in January and the old plants allowed to remain. In about three weeks from the time they were beheaded the auxiliary buds will begin to swell (of course the time will vary in proportion to the temperature in which the plants are growing), then it is that the bud may safely be removed, for at this stage they root readily and are soon in active growth. The plants may be cut into single eyes, leaving a leaf with each. As soon as detached from the old plant I thrust the cuttings into some dry silver sand, which stays considerably the flow of the milky sap which exudes from the cut ends. The cuttings may now be potted into 2½-inch pots, using loam and peat in equal parts, making it rather sandy; press firmly, and in some cases it will be necessary to employ one or two small crocks to keep the cutting in its place, and owing to the naturally short-jointed cuttings, two small sticks in an upright position should be used; secure the leaf loosely between these and there is no further fear of its removal. Plunge them in the propagating frame in the bottom heat referred to above, when in from fourteen to twenty-one days the majority will have formed roots, and may be seen on the surface of the soil. If they receive a thorough watering at first they will not require another for a week or more.

There is one other point, of only minor importance probably, and that is the splitting in halves of the larger pieces of wood; but having tried both ways I have failed to notice any benefit from splitting the stems, the main points being, as I have before stated, firm wood and plump eyes. When growth has fairly begun they should be removed from the bottom heat to a cool place near the glass, when a steady short-jointed growth may be secured, and as soon as fit give them a shift in 5-inch pots, and by the end of the season plants from 20 to 30 inches high may be had, adapting throughout the growing season the cool treatment, which will insure sturdy vigorous plants, well furnished to the pot with their broad handsome foliage.—J. H. E.

## BRIEF NOTES AT PARK PLACE, HENLEY-ON-THAMES.

A VERY agreeable hour was spent in a visit to these gardens, the residence of J. Noble, Esq.; and, though it was a wintry day, I found plenty that was interesting, respecting which the following brief and imperfect notes are submitted. The plant houses form an important feature, and in one of the first we entered, a compartment filled with cool Orchids, where *Cattleya intermedia*, *Masdevallia tovarense*, *Odontoglossum*, *Uro-Skinneri*, amongst others, are in flower. In the following

compartment *Angræcum sesquipedale* is very fine, also *Phalænopsis Schilleriana* showing a spike with fifty-five or sixty flowers, *Dendrobiums* in variety in large numbers, with fine well-ripened growths. In this house *Vanilla aromatica* is quite at home, showing about a dozen bunches of fruit. We must not omit to mention some fine examples of *Cœlogyne cristata* *Lemoniana*, several being fully 2 feet across; also quantities of *Calanthe Veitchii* and *vestita*, very bright. There are some remarkably strong *Lapagerias rosea* and *alba*, which are intended to cover the roof; the red and white are planted alternately, and are throwing up stout shoots. *Thysacanthus rutilans* is flowering freely. The plants are in 5-inch pots suspended from the roof by thin wire, presenting a novel appearance, the racemes of red flowers hanging considerably lower than the pots. An extremely fine healthy example of *Stephanotis* covers the roof of one house, and the platform is filled with healthy *Gardenias* for succession. These are chiefly in 6-inch pots. Useful table plants and *Euphorbia jacquiniæflora* are well grown. Palms and winter-flowering *Begonias* receive much attention. There is a pretty aquarium, well furnished with *Nymphæas* and other aquatic, with ornamental fish in abundance. One house is filled with a useful collection of *Camellias* flowering freely; another with *Tree Carnations* of the most popular varieties, which have almost completed their work for the season. Roses, however, will soon take their place. *Hoya imperialis* and *Allamandas* planted out cover the roof in another house, where some fine *Bananas* are also grown, besides *Gardenias* just commencing to flower.

The houses containing fruit trees are numerous. The first is a fine structure, 100 feet in length, filled with *Cherries* trained to the rafters, with pyramid *Peaches* between; a fine stock of *Figs* in pots is grown also, all in the best health. Vines in pots are promising well; when finished they are taken to the conservatory to furnish pillars. There are also some promising *Tea Roses*. A house is devoted to *Figs* planted out, but much confined at the roots, as Mr. Stanton, the able superintendent, considers that he gets much better flavoured fruit in larger quantities by this means. In the same range is a late vinery newly planted with *Black Hamburgh* and *Buckland Sweetwater*. An early vinery contains *Muscats* and *Gros Colman*, and another contains late Vines. Spaces to answer for shelves are left in the brickwork of the back walls of the whole of these houses for *Strawberries*, *Violets* in pots, &c. *Peaches* are in flower in the next house, and there are some fine *Shaddocks* on the back wall. There are other vineries, but I specially noted a *Peach* house in which are some fine specimens of *Eupatorium odoratum* about 4 feet high and as much in diameter. In one large house the roof is also covered with *Cherry trees*, all the best varieties being grown there. *Lady Downe's* is much prized as a late Grape, of which Mr. Stanton has a fine lot in bottles. A few *Alicante* are yet left, and some *Muscats*. A collection of *Grapes* for trial is grown with *Peaches* beneath running across the border, having quite a novel appearance, and seem to be very healthy. *Roses* are grown on the back wall of this house. Quantities of other plants for early flowering may be found in all the vineries in different stages. The fernery is placed beneath the conservatory, and is very charming, mirrors being so arranged as to make some very pretty views.

A very noticeable feature is a fine hedge of *Thuja borealis* dividing the fruit garden from the space allotted to the glass. The fruit garden is very complete; handsome trees trained in various ways clothe the wall, all available space being covered with fruit of some description, cordons being used on the small spaces round the houses, offices, &c.—J. P.

#### STIRLING HORTICULTURAL ASSOCIATION.

THE members of this Society assembled on January 28th in considerable numbers at Dowdy's Temperance Hotel, Stirling, to hold their anniversary meeting. As has been usual on such occasions, they took tea together and afterwards discussed topics relating to horticulture. Mr. M. Temple, Caronhouse, a new member, was requested to give an address on any subject suitable to such an audience. He took up points in relation to the progress and retrogression of horticulture during the last quarter of a century. Nothing was advanced as being derogatory to practitioners at the present time, but much sympathy was expressed for the men who were almost crushed out of their calling by the great reduction of gardening establishments, and the scanty allowance of means to maintain many gardens which at one time were among the leading places in the kingdom. England had suffered severely in this respect, Scotland was now following suit, and Stirlingshire was not exempt, numbers of the older places having been reduced to a nominal position so far as gardening was concerned, many being let, others standing tenantless. A high compliment was paid to many of the cultivators around Stirling, especially as cultivators of *Orchids*, some of the finest private collections in the country being in that district. Horticultural writers of the present time were complimented as men who wrote from their own practical experience, and many of them had shown what they could do by placing examples of their work on exhibition tables. Writers in times gone by often put voluminous matter before the public which was not from their own practical experience.

Exhibiting had its share of comment; and while large collections of plants of smaller size now occupied the tables at leading shows, large specimens of stove and greenhouse plants were scarce. Reference was made to certain growers of these whose names were once household words; but now few of the men who thus distinguished themselves were to the fore, and such plants as they cultivated are rarely seen. Among the specimens from the stove were huge *Allamandas*, *Dipladenias*, *Stephanotis*, and *Ixoras*, with perfect foliage and loaded with bloom. Greenhouse plants, too, were reported as being equally fine, *Pimeleas*, *Aphelexes*, *Boronias*, *Leschenaultias*, *Lapagerias*, *Chorozemas*, *Azaleas*, and *Heaths* having honourable mention as being among the princes of plant specimens. Those which have suppl-

mented these had special notice, numbers of foliage plants being among them.

Referring to the florists' flowers, it was stated that improved taste in many respects had been the means of crowding out such flowers as the great breadths of *Dahlias* which were once so common in the north. *Roses* had improved much both in varieties and cultivation, but many of the old favourites still held their own. The reintroduction of herbaceous plants and the exclusion of a large portion of tender kinds, which give much labour and short duration of bloom, was considered wise, and allowed the cultivator time to attend to other matters. Cut flowers and plants for indoor decoration had for some years taken much labour and expense, but owing to the depression of trade and the misfortunes attending agriculture many places had been reduced. A comparison of marketmen's advantages in the production of flowers over that of private growers was made a strong point, reference being made to a once large establishment which gave supplies in immense quantities, such as Mr. Temple had seen in no private gardens. Means were simple, but most efficient for its purpose, and each class had quarters to itself and treated as they required. *Gardenias*, both as market plants and stock for cut blooms were minutely described, and said to be easily kept free from insects. Steam from the manure linings is a powerful agent in maintaining free growth and keeping insects in check.

Vegetable-growing came in for its share of consideration. Vegetable exhibiting was much improved within the last score of years, but the majority of kitchen gardens had suffered from a reduction of labour and means in general. Skill and energy of cultivators had not deteriorated. Fruits, both hardy and forced, had not made much progress. *Black Hamburgh* and *Muscat Grapes* in first-rate condition were not proportionately so numerous as they were twenty years ago, but the larger, coarser, and "keeping" varieties were cultivated to a much greater extent now than formerly. Among other branches of horticulture landscape gardening had a special attention. It was pointed out that this had been much neglected. Reference was made to the work of Capability Brown at *Blenheim*, *Burleigh* near *Stamford*, and elsewhere, and that of later date by the

Fig. 17.—*Cephalotus follicularis*.

veteran Mr. Marnock, who received high commendations, and was considered one of the most distinguished of Scotch landscape gardeners. Severe criticism was made on the twisting of sheets of waters (such being carefully avoided by the two men referred to) and calling them "lakes;" cutting up lawns, calling such flower gardens; shutting out tracts of fine country, &c.; and the calling heaps of stones rockeries. Mr. Temple received a very hearty vote of thanks at the conclusion of his address.—J. R.

#### CEPHALOTUS FOLLICULARIS.

THIS pretty and interesting little plant is a native of Australia, where it was first discovered by Labillardière, who described and figured it; subsequently Mr. Robert Brown also found a specimen during his voyage with Captain Flinders. It was first cultivated in England about 1822, and is now by no means a rarity. The plant is remarkable in several ways, for it is the only species of the genus, and is considered sufficiently distinct to constitute a natural order (allied to the *Polygonums*), and we thus have the peculiarity of a family composed of one individual. In the leaves, too, we find another singular feature—some are flat and elliptical in form, while others are converted into extremely neat and pretty little pitchers or *ascidia*, somewhat resembling those of *Nepenthes*, only much

smaller. They are dark green with a purplish shading, and pink veins, and are furnished with small lids, the mouth of the pitcher being bordered with a dark-coloured furrowed ring.

This *Cephalotus* is an inhabitant of marshy land; it should therefore be provided with a soil composed of peat and live sphagnum moss, the pot being well drained and placed in a shallow pan containing water. If the plant is grown in a pan, that should be placed inside another larger one, the space being filled with fine Derbyshire spar and kept constantly moist. In either case a bellglass should be placed over it. The best position and temperature is the cool end of the stove or Orchid house, where with careful attention in supplying the requisite moisture the plant will grow freely.

**ORANGES AND PINE APPLES.**—In an official report it is said "The falling off in exports from St. Michael's to England, especially during the past ten years, is, I have good reasons for believing, to be largely due to the increased production of Oranges in the south of Spain, which has competed with the fruit of the Azores throughout this period. The season of 1873-4 saw the English markets glutted with large importations of Oranges; in the season of 1884-5 the export of the same fruit from St. Michael's was the worst recorded for the past forty-two years. Cultivators are disheartened, and those who have not already succumbed to its effects have cleared their land of trees, and planted it with cereals and the Sweet Potato. In striking contrast to this rapid decline in the Orange trade is the marked increase in the value of the Pine Apple export. Increasing attention has been given during the last fifteen years to the cultivation of the last-named fruit; and the exportation last year reached 184,400 Pine Apples, of an estimated value of £19,699."

#### KITCHEN GARDEN.

**THE WEATHER AND WORK.**—Of late the weather has been decidedly against work in the kitchen garden. We have had more frost, snow, and severe weather in our locality this winter than has been experienced for some years, and from all we hear this is the experience of many others. It will not be an early spring, but the complete rest which vegetation is now enjoying may induce rapid and luxuriant growth when genial weather returns. All those from whom a supply of vegetables are expected must begin planning how best to advance them. Sowing in the open ground just now is impossible, but thousands of plants may be raised under glass in a very little space; cutting boxes are most useful for this purpose. If several of them, from 2 feet to 3 feet in length, and 1 foot or more in width, are sown with Cabbages, Cauliflowers, Letuces, Onions, &c., the plants will be in good order for placing out in a month or six weeks. Fill the boxes with good soil, sow the seed thinly, only force them when quite young, harden them well, keep them near the glass in a cool place when they are 2 inches high or so, and anyone who walks round the garden in April will be unable to say that the weather has retarded any vegetables. We prefer open air culture to all others, but when we see this cannot be managed with advantage, we resort to the underglass systems, and these are in operation with us.

**FRAME CARROTS.**—In April and May these are greatly valued, and we would advise all who have the means of making a hotbed, and can place a frame on the top of it, to sow at least one frame of Carrots. The present is a profitable time to sow. Make up a good hotbed, put the frame on the top, and then fill in the soil. In the park close by the moles have been at work; they have thrown up some excellent soil, and this we have wheeled in for the frame Carrots. Being friable it suits them well. It should be mixed with a liberal quantity of sand, a little soot, and some well-decayed manure. Soil 6 inches deep is quite sufficient to bring all the Horn varieties to perfection, but it ought to be trampled very firmly, and the seed be sown thinly broadcast. We always cover the seed with sea or river sand, and this keeps the surface sweet. The lights are placed on immediately sowing is done, and air is admitted on fine days. Those fine Carrots which are often seen at early shows are raised in frames in the way we suggest, but for the Intermediate the soil must be about 1 foot in depth. Those who wish to show fine Carrots in May and June ought to make a substantial hotbed and sow at once. We have just sown seed in three large frames, two for the kitchen, and one for show roots. The former are Early French Forcing, the latter an Improved Intermediate sort.

**DWARF FRENCH BEANS.**—Make a very large sowing of Cooling's Ne Plus Ultra. With gentle forcing they will be ready for gathering about Easter, and they will be very valuable in the market then and acceptable in the kitchen. Put from eight to ten seeds into a 3-inch pot, employing rich soil, and allowing them to become about 4 inches high in these before shifting into larger pots. We have tried growing them early in narrow boxes, but they never succeeded like those in the pots; and

although the pots require more space than the boxes, the extra good crop secured more than compensates for this. Plants raised from seed during January will grow slowly, and it is better not to force them too hard, as this will only cause them to grow weakly and spindly, and when this happens they do not fruit freely. In potting, use rough soil and horse droppings, and be careful not to supply too much water, as the young plants are rather apt to suffer from this during the short days.

**MUSTARD AND CRESS.**—Those who gave up growing these during the shortest days may take to them again, as they grow more freely now than in December, and as other salads may be becoming scarce the Mustard and Cress will give satisfaction. Sow in the usual manner in shallow boxes filled with any kind of soil and place in a temperature of 60°. Fanciful persons sow in soup plates, placing them on the table full of growing plants.

**POTATOES.**—Plant more in frames as suggested on January 7th. Probably those put in now may be ready for digging as soon as any put in some weeks ago. Admit a little fresh air to those through the soil when the weather is favourable, but do not give them any water. Cover with mats when it is frosty, and do not allow them to be checked in any way. Early varieties in their store places are now sprouting and require attention. They should all be placed in trays or shallow boxes one layer deep, and placed in a cool position fully exposed to the light. So long as frost is excluded that is sufficient, as the object is to secure dwarf sturdy shoots, and these are only formed in the light. Those tubers intended for immediate planting may receive different treatment by placing them in boxes, shaking a little sand or leaf soil over them, and then place them in a temperature of 55° near the glass to sprout freely. Later varieties which may be pushing shoots owing to being in a warm place must be turned over and the shoots removed.

**PEAS.**—Give those above ground a dressing of guano, then earth them and stake them carefully. Sow more seed of the earliest varieties, such as Ringleader or William the First. They will soon grow in the open and prove a useful succession to those up now, or others which may be raised under glass. In many gardens, especially large ones, the practice will now be coming into operation, and it has its advantages. Success all depends on growing them slowly and keeping them dwarf. If they are drawn up in a strong heat and a long way from the glass they will never prove remunerative. The best way is to sow a dozen seeds in a 3-inch pot, start them into growth in a gentle heat, and when about 2 inches in height place them in a cool atmosphere near the glass. In this way capital plants for placing out about the middle of March will be obtained. Where frames are plentiful seeds of American Wonder may now be sown in them. Give plenty of rich soil, and do not use deep frames, as it does not exceed 1 foot in height, and when in full crop the tops ought to be close to the glass.

**ASPARAGUS BEDS.**—These should now have a rich top-dressing. Many never think of doing this until they can see the young heads coming up; but it is late then, and now is the time to apply it if the fullest benefit is to be derived. Where the soil is light place a good layer of rich manure over each crown and wide enough to cover the roots. In heavy soil do not use manure of an ordinary kind, but apply a heavy sprinkling of guano mixed with an equal quantity of salt and soot.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Earliest House.*—The past month has been unfavourable to forcing operations. Where, however, extra attention has been given to fertilisation, and the maintenance of low steady heat, particularly at night, there is every reason to anticipate a good set of fruit. If there are any late-blooming varieties it is likely they may still be in flower, and these must still have the camel's-hair brush passed over them daily, and the house kept moderately dry with a moderate circulation of air until the flowers begin to fade, when a slight syringing with tepid soft water will soon bring off the remains of the flowers, and set the mind at rest with regard to the first stage, which always, especially after a period of bad weather, causes anxiety to the cultivator. Peach trees in inside borders always do better than those having the roots in cold outside borders, and they will set in a lower temperature, and make up for lost time as days increase in length and brightness. It is best to follow the old sure method, as nothing is more annoying than the loss of a crop through undue haste. Proceed with disbudding cautiously; also shorten shoots that were left of full length at pruning time. Take off the foreright shoots first, commencing at the most upright parts of the trees, and work down to the horizontal branches at the base. Keep a sharp look-out for aphides, and fumigate upon their first appearance. Be careful, however, not to give too much, as the foliage and tender fruit are very susceptible of injury. See that all surfaces near hot-water pipes are kept constantly moist, and that the roots of the trees are well supplied with tepid liquid manure in a weak state. Make frequent additions of fresh horse droppings for giving off ammonia and acting as a check to red spider; but on no account must these or heavy mulchings be given until the stoning process is effected. Admit a little air on all favourable occasions, but be careful to avoid cold currents, and close sufficiently early to raise the temperature 10° to 15° from sun heat.

*Succession Houses.*—The trees now approaching the flowering stage—indeed those started early in the year—have the blossoms expanded, and will need less moisture, syringing directly over the trees being discontinued, but secure a genial condition of the atmosphere by damping occasionally. In other cases syringe well until the blossoms commence opening, and in case of a great show of blossoms remove those on the

under side of the trellises. Do not omit to fumigate on a calm afternoon when the trees are dry to destroy any aphides that may exist, and so keep the trees free from these pests until the flowering is over. If there be any doubt about the moisture of the inside borders give a thorough supply of tepid water, or weak liquid manure if the least indication is seen of impaired vigour in the trees from repeated forcing.

**Late Houses.**—The severe weather has kept the blossoms of the trees in these back, but as the wood was well ripened, and due attention has been given to watering the inside and protecting the outside borders, judicious ventilation will keep the trees in condition for giving full crops of fruit. Where the lifting and re-arrangement of trees in late houses has not been completed it should be brought to a close as soon as the weather permits, but on no account should the borders or trees be interfered with in bad weather, as working the compost when wet only converts it into mud and a soddened sour mass.

**MELONS.**—To achieve a quick but at the same time a sturdy growth the cultivator must have at command sufficient top and bottom heat, and by ventilating on all favourable occasions, closing early with genial atmospheric moisture on bright days, a quick, sturdy, and consolidated growth will be obtained, on which success in all fruit culture, especially with Melons, depends. Great care must be exercised in ventilating, a current of cold air being very injurious; hence a piece of hexagon netting should be placed over the ventilators when the days are bright, but the air cold.

Cover dung frames with double mats at night, and in case of very severe frost some dry straw or fern. See that the linings are regularly attended to, removing the old as necessary, and supplying with fresh material. Sow as occasion requires for successional crops, always taking care to have more plants than are likely to be required.

**CUCUMBERS.**—Keep the night temperature at 65° to 70° and 75° by day, with 80° to 90° with sun heat, closing early in the afternoon with plenty of atmospheric moisture on bright sunny afternoons. This, with judicious applications of liquid manure in a tepid state to the roots, will cause the plants to make free growth. Cropping lightly and keeping the plants clean are essential to free successional fruiting. Avoid overcrowding, keeping the foliage thin, removing bad leaves and exhausted growths, and stopping others one or two joints beyond the fruit as space allows.

Young plants are now ready for transferring to the hillocks in the Cucumber house, it having been thoroughly cleansed, and the soil placed in a few days previously to become warm. Press the soil firmly about each plant, place a stick to each, and fasten it to the first wire of the trellis. Should there be bright sunshine at the time of planting, give a light shading in the middle of the day, from about 10.30 A.M. to 1 or 1.30 P.M., to prevent flagging, after which it can be discontinued, and the plants subjected to the full influence of the sun's rays.

The linings of dung frames in which Cucumbers are growing will need to be attended to weekly or fortnightly according to the state of the weather, keeping a supply of well-mixed dung and leaves in readiness for that purpose.

**STRAWBERRIES IN POTS.**—The weather has been such as to barely admit of more than keeping the plants gently moving. Ventilate cautiously, and under or above the plants, so that it is warmed before it comes in contact with the flowers, and when the air is cold and sharp have some hexagon netting placed over the ventilators. Water plants in flower on the mornings of fine days, lifting the leaves and flowers with one hand, so as to avoid wetting them, and keep the water from the crown, as that sometimes suffers through the frequent applications of water and a close atmosphere. Have the atmosphere rather dry for a couple of hours each day, so as to insure conditions favourable for fertilising by a little extra heat if necessary with freer ventilation. Fertilisation is quickly effected with a featherduster, examining the flowers each day, until there is a good crop set, after which remove all superfluous flowers and deformed fruits. Introduce more plants for successional fruiting, according to the space at command and the requirements.

#### PLANT HOUSES.

**Adiantums.**—Some plants should be pushed into growth without delay where a continuous supply of fronds in suitable condition for cutting is required daily. Plants from which fronds have been used during the winter have commenced pushing up new ones freely if they have not been in a lower temperature than 50°. Those most advanced should be placed in a slightly warmer house, and in a very short time a mass of developed fronds will be produced. After growth has fairly commenced the plants may be divided and repotted if they need more root room. For this purpose the majority of our plants are in 5 to 7-inch pots, and after the pots are full of roots each plant is cut into two and then replaced into the same size pots. By this method more roots are undisturbed, and the plants starting quickly freely again into growth. As soon as they are growing and rooting freely in the new compost they are placed in a light airy structure where the night temperature ranges about 55°. *A. cuneatum* is the most serviceable for this purpose, and if the fronds are to last well after they are cut they must be developed under the influence of light and abundance of air. Other varieties where large fronds are required for other purposes may be treated in the same manner. A very suitable compost for these plants is fibry loam, one-third leaf mould, and a liberal dash of coarse sand. Leaf mould for these plants is preferable to peat.

**Plants in Baskets.**—It is surprising what a number of fronds can be

obtained from plants grown in wire baskets 8 or 10 inches in diameter suspended from the roof of plant houses or even vineries. *Adiantums* do remarkably well in baskets, and will yield the requisite material for cutting without taking up the stage room of plant houses. When dividing the plants, if good portions are placed in baskets and grown on through the season they will be fully 2 feet through by autumn. For two or three years the plants will do well in baskets, and by that time they will be a mass of roots and should be turned out, divided, and given as much fresh soil as the space in the baskets will allow. During the summer these plants may be suspended in any cool house, but after the fronds have been gathered in autumn they must not be kept in too low a temperature during the winter, or else they will not start freely again in spring. The same soil should be used for these as when the plants are grown in pots, only it will be necessary to use fibry peat towards the outside of the baskets.

**Davallias.**—Such species as *D. bullata*, *D. canariense*, *D. dissecta*, *D. Mariesi*, *D. Tyermanni*, and others may be more successfully grown in baskets for supplying fronds for cutting than is the case in either pots or pans. Those named can all be grown successfully in the greenhouse; in fact, will bear during the winter the low temperature of a vinery without the slightest injury. For these plants baskets slightly larger should be employed, for under good cultivation their creeping rhizomes will soon take possession of the whole of the outer surface of the baskets, and when in this stage they are very beautiful suspended in any plant house. Although these do well under the conditions indicated, they enjoy a little heat to start them into growth, and by this means fronds are ready for use much earlier in the season than would otherwise be the case. The fronds of these plants are invaluable for cutting when grown under cool moderately light conditions, for they remain perfectly fresh for a long time after they are severed from the plants. When grown in heat they are much subject to the attacks of thrips, which is not the case when grown under comparatively cool conditions and liberally syringed. For these plants we prefer a compost of equal parts of peat and fibry loam in a rough state with charcoal freely intermixed. Stove varieties are also very handsome and useful in baskets, especially *D. Mooreana*; these may be placed in them at once, or divided as required.

**Selaginella coesia.**—This is a charming plant for furnishing purposes, and may be most effectively used for a front edging in the stove, intermediate house, or even the conservatory, during the summer months. When used alternately with *Panicum variegatum* the effect is all that can be desired. For these purposes plants are the most suitable in 4-inch pots, and cuttings of *Panicum* can be rooted in the same size for association with them. During the winter this *Selaginella* can be accommodated in any cool position; in fact, our plants are generally kept in a cold vinery. If placed in a temperature of 50° they will commence growing at once, and in about a fortnight from the time they are started may be divided and potted in the size required. Each plant grown for a season in this size will make three or four quickly when divided, therefore it is unnecessary to keep a very large stock through the winter. These plants grow well in loam, leaf mould, and sand.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

**Propagating Summer Bedding Plants.**—It is a mistake to sow the seeds of various bedding plants, with a few exceptions, very early in the year, as in this case they are liable to be too far advanced by the time bedding out commences, and a serious check to their growth may be given. Too often such free-growing kinds as *Ageratums*, *Petunias*, *Antirrhinums*, *Pentstemons*, *Dahlias*, *Pyrethrum*, are sown very early in the year only to remain in a crowded state in the seed pans, till they have become drawn and almost worthless. Annuals, especially such as *Stocks*, *Asters*, *Marigolds*, *Zinnias*, *Dianthus*, and *Godetias*, ought not to be raised long before they are planted out, as anything in the shape of a check to their quick sturdy growth is certain to materially detract from their usefulness and beauty. In due course all the popular kinds will be again alluded to, and the methods of raising and growing them we have found perfectly successful will be given.

**Tuberous Begonias.**—These are now found of great service in the flower garden, no class of plants succeeding better in dull wet weather, and during more favourable weather they almost equal the *Zonal Pelargoniums* for brilliancy. Seedlings may be raised and planted out the same season with good effect, but one-year or two-year-old tubers are most suitable for bedding out, especially in prominent places. It is very unwise to sow seed saved from common or inferior varieties, the more compact strains, and which produce finer better shaped blooms, being by far the most effective in the flower garden. Sow the seed at once on the surface of a pan of fine peaty soil, or, what will do quite as well, a mixture of fine leaf soil and sifted loam. Make this rather firm and quite level, moisten it through a fine-rose watering pot, sow the seed thinly and evenly, and sprinkle over, but not so as to bury it deeply, a little fine silver sand. Stand the pan on a mild hotbed, cover with a square of glass, and shade heavily till the seedlings are up, afterwards from bright sunshine only. They must be kept uniformly moist, care being taken not to wash them out of the soil, and they should be pricked out in boxes of fine light soil before they spoil each other in the seed pans. Keep them growing in a warm house or frame till the middle of April, when they ought to be large enough to prick out in a frame of good soil disposed on a slight hotbed. From this they will transplant readily. Old bulbs ought to be allowed to start naturally either in boxes of good soil

or in frames, and, as a rule, will be of good size by the time they are wanted. To start them early and in heat spoils them for bedding out.

*Lobelias*.—In many gardens these are planted out extensively, and propagating has to be commenced early in consequence. When there are plenty of stocky old plants these yield abundance of good cuttings, or they may be split up into small pieces each with a few roots attached and dibbled into boxes or pans of fine soil and kept growing in a gentle heat, such for instance as an early vinery or Peach house. Cuttings, if not too hard or "wiry," strike readily under handglasses on a hotbed in boxes of soil and covered with glass or in ordinary propagating frames, care being taken to dry the glass every morning if damping off commences. Rooted cuttings should be first dibbled out into shallow boxes of fine good soil, and later on be temporarily planted out into frames, where they will become large plants by bedding-out time, the rooted divisions also being improved by similar treatment. Where there are no old plants the stock must be raised from seed. Seedlings are usually more vigorous and less compact than plants raised from cuttings or division; but for large beds or for edging other stronger-growing bedding plants they are effective enough. All the leading seedsmen now supply good selected strains of *Lobelia speciosa*, *L. pumila magnifica* and *L. Erinus* varieties also being reliable. In order to secure strong plants the seed should be sown early. Being almost or quite as minute as *Begonia* seed, it should be treated exactly the same, subsequent treatment also being much the same.

*Centaureas*.—Although very effective these are not so much grown as they were, chiefly owing to the difficulty often experienced in wintering a sufficient number of stock plants. Strong cuttings taken off with a heel dibbled thinly in pans of fine sandy soil, and plunged in or stood on a brisk bottom heat, soon strike root; and if the operation is delayed till March or early in April many of the side shoots, and which only are suitable for propagating, may be taken off with roots already formed. We do not attempt to winter stock plants, preferring rather to raise the number of young plants required from seed. As they are rather slow growing, the seed is best sown early in February thinly in a pan or pots of light soil and plunged in a mild hotbed and covered, after being watered, with squares of glass, the latter being gradually removed after the seedlings appear. They are best not disturbed till they are about 3 inches high, when they may be placed singly into 3½-inch pots, any light loamy soil, with a little Mushroom bed refuse for drainage suiting them. They must be still kept in heat till well established, when they can be gradually hardened off. If finally planted in fairly rich soil they soon attain a good size, growing more rapidly than plants raised from cuttings. *C. candidissima* is the most compact in growth; *C. Clementi* and *C. gymnocarpa*, the former growing 2 feet in height and the latter rather less, being also very desirable either for ordinary or sub-tropical bedding.

*Chamæpseue*.—There are two sorts of this Thistle-like plant suitable for bedding out, both of which are raised from seed exactly as just recommended in the case of *Centaureas*. *C. diacantha* has silvery spiny foliage, and is the most generally grown, but *C. Cassabona* with green spiny foliage is also very pretty and useful. Both may be employed in carpet beds with advantage, a few plants being kept in pots to replace any that may die prematurely, as they are unfortunately somewhat liable to do.

*Cannas*.—Those who have a number of strong clumps of these stored away may, if they wish to, safely split them into nearly as many pieces as there are young growths; this being done later on. If there is none in stock, then, in order to have a few for sub-tropical beds, and where they are remarkably effective, procure some seed. This is extremely hard, and to insure quick germination must either be soaked in warm water for several hours or till softened somewhat, or they may be filed through sufficiently to admit of the germ bursting its way through. The seed in either case being sown in pots or pans of peaty or light soil, should be plunged in a brisk bottom heat and watered with warm water. When the seedlings begin to unfold their first leaves they may be transferred singly into 3-inch pots and given a shift into 6-inch pots later on, or they may be placed at once into 5-inch pots. Good fairly light soil suits them, and they should be kept growing under glass till late in May, and be finally planted out before they become badly root bound. *Canna* seeds can be purchased in collections of separate varieties or singly, some of the best sorts being *Annei*, *Chateri sanguinea*, *grandiflora floribunda*, *maxima*, *nigricans*, *sanguinea*, and *zebrina*.

*Grevillea robusta*.—This is a rather slow-growing green-foliaged plant, very durable and fairly ornamental. Seeds sown in a pan of light sandy soil, plunged in a hotbed and covered with glass, frequently germinate satisfactorily, and if the seedlings are placed singly into 4-inch pots they will attain a useful size by the time they are required. As a rule they are of most service during the second and even third years, and can be wintered among the conservatory plants.

## THE BEE-KEEPER.

### INITIATORY INSTRUCTIONS.

A CORRESPONDENT and reader of this Journal is desirous for his own and others' benefit to be instructed in the rudiments of bee-

husbandry and of the Stewarton hive, as hitherto I have been too far advanced for beginners. As there is no royal road to learning bee-keeping, neither is there any first lesson to give, at least I am ignorant of what the first lesson in bee-keeping is. As regards the legislators introducing the subject of bee-keeping into elementary schools, I consider is at present not feasible, as there are too many widely differing opinions on the principal points of bee-keeping. "Felix's" remarks on pages 55 and 56 are good. My previous silence on the subject arose entirely through the absurdity of the proposal, apart from the scientific questions of bee-keeping, which is one for the study, not for the school. There is already by far too much teaching in schools in committing to memory that which is of no present and little future use. Teach by varied reading as much as possible, but commit to memory only that which the pupil will be benefited by in after life.

At page 56 there is an illustration of the mischief wrought by the teachings of the leaders in bee matters differing from each other. This was caused by ignoring the advice frequently given in these pages, and "Plus" has thereby brought the calamity on his hive. I can fully sympathise with "Plus" in the loss of the bees, and am also cognisant of the dilemma bee-keepers are placed when two widely different plans of management are given by two persons. In the case mentioned by "Plus" the bees were removed 300 yards at the end of September, and since then there have been many opportunities for the bees to air themselves. When they did so they simply returned to their old site, and not finding their hive perished. For some time before January the weather was very mild, and the bees were active everywhere. Those that were seen flying about a week or two ago were robber bees, and not those of their own hive. The foregoing introductory remarks have not been made solely for the information of "Plus," but for all others who are seeking it, and particularly for those wishing for initiatory instruction. It is rather tantalising after one has given all instructions to find that they have been ignored.

When I am in a fix, not knowing how to act for want of knowledge, a lesson from Nature direct often gives the hint desired; when the lesson is ignored, resulting in loss or pain, we become doubly impressed with its importance, and better care is taken in the future. I am inclined to think that the natural history of the bee should be partially known by the intending bee-keeper, and that the subject should be thoroughly studied by experimenting thereafter; not that by so doing and gaining knowledge thereof better results are to be expected, but that by having a thorough understanding of the natural history of the bee much after-disappointment is prevented, difficulties are more easily overcome, and mishaps can be rectified in time to prevent disappointment and loss.

Supposing, then, that our pupil is already posted up in the rudiments of the natural history of the bee, and that he possesses one or more hives of bees in straw hives, he need not bother himself much about having ocular demonstration of the sting, the bees will very soon let him feel it; and if he is anxious to try the inoculation theory he has only to try one of the latest nostrums as a bee-quieter—viz., vinegar: rub some of it on the exposed parts of the body, and the bees will not be slow in using their stings. Repeat the operation, and he will soon learn the fallacy of inoculation lessening either the pain or swelling. If on being stung serious symptoms set in use means to bring about perspiration, apply camphorated oil with friction to the throat and upper part of the chest, inhaling and swallowing some sal volatile at the same time. It being next to impossible to intercept the flow of the virus into the blood after being stung, bleeding immediately after the sting alleviates both pain and swelling. Some people are not affected by stings, those may prosecute bee-keeping with safety; but all those who are seriously affected should not incur risk by keeping bees. Some people become greatly disfigured by the swelling, but are not otherwise seriously affected, therefore all such need not be troubled by the little unpleasantness.

To learn how to approach and manipulate the bees, and to know the time to manipulate when bees are not inclined to sting, are cardinal points for the novice to learn. The first should be done in a quiet, yet bold, but steady manner, wearing clothing free from smell or perfume of any sort, the skin being the same. If attacked by the bees veil at once, and approach the hive with carbolic acid, using it judiciously on the alighting board and the front of the hive until subdued by smell only, as its touch kills the bees. All manipulations should be performed while the bees are under the influence of the acid, and in such a manner that not a single bee is killed. The best time to perform any manipulation is under a temperature of 70° or more, and when the bees are filled with honey. It is highly disastrous if the bees are allowed to taste honey belonging to any other hive, it creates robbing and incites stinging.

Premising that all novices desiring information on the management of the Stewarton hive are well versed in minor details of bees

in straw hives, I will now proceed to the swarm issuing from a straw hive. Every thoughtful bee-keeper should have in readiness a few long rods, so that one of any length may be formed from these. On the one end of the rod a few feathers should be tied and saturated with carbolic acid. If the swarm attempts to settle on or in some inaccessible place the feathers held close to the place will dislodge them, and cause the bees to settle in a handier place near the ground. The sooner bees are hived after swarming the better, and should be at once placed on their permanent stand and in their permanent hive. Where the Stewarton hive is in use one or two boxes make a capital hiving box. After the bees are hived they are simply placed beneath those previously prepared with comb-foundation, where the bees ascend, when the under ones may be withdrawn. If it was not for fear of the comb foundation giving way I would use no other than the permanent boxes, but caution must be exercised.

I must, however, hark back and tell all about the hives, and where to get them. Messrs. G. Neighbour & Sons, 149, Regent Street, London, supply these to English and to the Channel Islands and Continental bee-keepers; Messrs. Warnock & Walker, Blantyre, whose advertisement appeared lately, is the oldest firm of hive-makers in Scotland, being established in 1835. These two firms are reliable, and bee-keepers will be well served by either of them. A passing remark about prices, and in justice to all concerned, may not be out of place here. I have examined goods from various firms, and find if one firm sells cheaper goods they are not usually of the same value. The cheap article is constructed of inferior material, and where much labour has been bestowed upon an article the price is often exorbitantly high. The difference in the value of timber hives are made from is about three and a half to one, so that where one maker produces an article at 12s. with but a moderate profit, another may produce the same article at a third that price with inferior material, but at a large profit, consequently it is the dearest. I write for the interest of bee-keepers and not of hive-makers, and I hope bee-keepers will weigh the matter well in their minds.

When new hives are wanted discard all those having sapwood, and give preference to yellow pine, which, though much higher in price, is more durable, and better adapted for hives and the health of bees than is yellow deal or white pine, termed in bee nomenclature pine. Both of these last mentioned are cheaper, but inferior to the first-named one.

When ordering Stewarton hives do not ask for less in number than three body boxes, with as many supers. If sections are desirable get the crates made to hold six in width, and there may be two or three of these that will project a little at the corners, which must be filled in. This applies only to the first tier. But sections are not the most profitable things to use, divisible supers are the best. There are the common Stewarton and the "Renfrewshire-Stewarton," the latter has four frames in the centre of each tier. There is also the square-tiering hive introduced by me, which, though faulty for wintering, in possessing the four corners, which is liable to cause damp, as all square and oblong hives do. The above fault is obviated if ventilating floors are used. All the top bars of hives should have a groove one-eighth wide by one-eighth deep for comb foundation. All hives deeper than 6 inches should have frames, hives less than that bars are sufficient. Slides of some sort, too, are indispensable in every hive; but the Stewarton proper has but the one sort of slide. The only material difference between one maker's hive and another is that the slide runs right through and requires double the number of pegs of those which are stopped by a permanent peg. The former sort is the best, because the slightest tap on the end slackens the propolis and is easily withdrawn. These slides, too, should be so close as to prevent the bees caulking the joint between slide and bar.

Difficulty in withdrawing the slides is only experienced when they have been made slack at first. Each hive should have a pair of strong iron handles screwed firmly to the sides, and no hive should be without a ventilating floor. An outside case of some sort or other is very desirable, but not absolutely necessary, as they can be well protected with straw; and hives so covered cannot be improved on so far as health and comfort of the bees are concerned as well as for ease of manipulation in putting on and taking off supers or otherwise increasing or diminishing the size of the hive.

When the bee-keeper gets his hives from the maker his first work is to put the comb foundation in. These should be an inch narrower than the depth of the frame or hive, but should almost touch the ends, after which two boxes should be lashed together, the under one fully pegged, and the upper one filled with slides between bars. It is now ready for the swarm as previously directed. Where a common floor is used three entrances are necessary in all octagon hives, but since the introduction of the ventilating floor one is sufficient.

After a swarm has been located in a Stewarton hive of two boxes several weeks, the weather being fine and honey in abundance, another good swarm should be added, and several honey boxes added at the same time. Should the weather continue fine on the expiry of a

week, these supers will be well advanced and another added above not between the others and stock hive, because if the weather changes the bees will attempt to fill up the vacuum they naturally abhor by combing the one interposed from the honey of those above, and if there is a scarcity of honey in the stock hive it may be carried down into it. With a continuance of fine weather after the first manipulation with supers the mishap may not occur, but we should never risk the spoiling of fine supers by interposing empty ones between the full ones and stock hive. The bees should be admitted to supers by outside spaces only in stock hive, but all slides should be drawn in supers. Perhaps the foregoing will assist the uninitiated, and as the year advances I will give further instructions how to join the swarms and manage as a non-swarming hive the following year.—A LANARKSHIRE BEE-KEEPER.

#### BEES ABANDONING A HIVE.

I THINK the cause of the bees deserting the hive as mentioned by "Plus" was in consequence of the loss of the queen; indeed, the bees did not abandon the hive, but died. I have had them apparently doing well until a late period, when they suddenly collapsed, and the invariable cause was loss of the queen, which had taken place some time previous, but the bees kept up an appearance for some time, and all apparently were going well to an inexperienced person, for as the bees diminish in number through death they show at the mouth of the hive; even a dozen bees make a great fuss at the mouth of a queenless hive, and some live on into the winter; indeed, I have had them exist in a state of defence well on into spring. I do not think bees desert their home so long as the mother remains, or if they do, as may happen through poverty in spring and when the colony is strong, yet there are means left of raising another mother in the stock hive, and so continuing its existence. These poverty swarms, I fear, are only a consequence of neglect on the part of the apiarian—neglect of feeding—but I have a tale to tell some day about such things.

I suppose "Plus" has no more hives, and there is none near, otherwise the hive would not have been found fairly filled with honey. Perhaps the queen has been lost late, which I hardly think, or the bees would have lived into spring. My bees do not tolerate a queenless hive long, for they allow no honey to escape carriage to their cells, all alike joining in the appropriation.—G. ABBEY.

BEES AND THEIR ENEMIES.—At the last weekly meeting of the Astwood Bank Mutual Improvement Society. Mr. James Hiam gave "A Chat on Bees." Mr. Hiam contrasted the old system of bee-keeping with the modern, pointing out the superiority of the latter. To illustrate his points Mr. Hiam was provided with a full supply of apparatus. It was stated that the comb was made from an exudation from the insect's body, and not from the pollen, as erroneously supposed. Pollen was collected to make bee-bread for the feeding of the young bees. The first swarm carried on work till the autumn, and the best honey was from the stock of the first year. A contradiction was given to the old belief that in swarming the queen led the way and all her family followed. Certain bees acted as leaders and selected a branch to settle on; the other bees followed, and the queen, finding her family gone, followed. As regarded the comb, the advantages of having a prepared foundation were the saving of much of the bees' time, and a less expenditure of honey. It was said that the bees consumed 20 lbs. of honey while making 1 lb. of comb. It was incidentally pointed out as a remarkable provision of Nature that the cells were in an upward direction, that position being better calculated to hold the honey safely. Mr. Hiam also said that, as far as his experience went, the neighbourhood was a poor honey district. The modern methods of "taking honey" and feeding the bees were fully explained and illustrated. After stating that the bees could make a queen from a grub by feeding it with queen bread, Mr. Hiam referred to the enemies of the bees. Wasps were given as the chief—viz., *Vespa Germanica*, *Vespa vulgaris*, and *Vespa Britannica*. The nests of these wasps were exhibited, and very fine specimens they were. The tomtit was defended from the charge of being an enemy, and Mr. Hiam assured his audience this little bird was most harmless. As on former occasions, Mr. Hiam preferred to treat the subjects on the conversational style, answering questions as they occurred during his address, instead of a string at the end. Thus a pleasant evening was spent, which was brought to a close by the Chairman, the Rev. W. W. Robinson, proposing a hearty vote of thanks for his instructive and interesting lecture.

#### TRADE CATALOGUES RECEIVED.

Edmondson Brothers, 10, Dame Street, Dublin.—*Spring Catalogue of Seeds.*

James Yates, 29, Little Underbank, Stockport.—*Catalogue of Flower and Vegetable Seeds.*

Ralph Crossling, Penarth Nurseries, South Wales.—*Catalogue of Vegetable and Flower Seeds.*

Robert Craig, 90, Stricklandgate, Kendal.—*Catalogue of Vegetable and Flower Seeds.*

Viccars Collyer & Co., Leicester.—*General Catalogue for 1886.*

W. Crossley, 13, Vicar Lane, Leeds.—*Catalogue of Vegetable and Flower Seeds for 1886.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**A Variegated Tropæolum (M. H.).**—We grew a variegated form similar to one you sent, some years ago for edgings in a flower garden, but the plant was dwarf in habit, and not "running" as you describe that you have raised. The leaves on the shoot sent are neatly variegated with white or cream, and it is certainly worth preserving.

**Cauliflowers and Broccoli for Succession (O.).**—Walcheren Cauliflower sown in February will come in in July and August; sown in early April heads will be produced in September, and a sowing made at the beginning of May will afford heads at Michaelmas onwards. Veitch's Self-protecting Autumn Broccoli should be sown in early April for affording a supply of heads in December onwards; and if at the same time be sown Cooling's Matchless, Leamington, and Lauder's Goshen Broccolis for a supply in spring up to May, there will be no difficulty in keeping up a succession.

**Choisya ternata (E. D. O.).**—You are slightly in error. This is not a new plant, but was introduced from Mexico in 1825. It has been much more extensively grown during recent years, and since it was found so well adapted in a small state for conservatory decoration. Plants are very extensively raised and grown on the Continent, planting them out, with Azaleas, in beds of sandy leaf soil in the open air and potting them in the autumn. They produce white flowers plentifully in the spring, and flowering plants are now to be seen in Covent Garden Market, but this is very early for them. *Choisya ternata* is very well worth growing for the purpose indicated.

**Chloride of Lime (S. M.).**—Chloride of lime, or bleaching powder, is composed of chlorine 36.23, lime 36.77. Exposed to the air, it is converted into chalk and muriate of lime, a salt which absorbs moisture from the air very powerfully. By this conversion it becomes a useful addition to soils; and, as it also gives out some chlorine gas, so offensive and destructive to insects, it has been suggested as a useful application to the land at the time of Turnip sowing. It is also useful as a disinfectant, and for sprinkling about stable floors to fix the ammoniacal fumes.

**Eucalyptus Leaves Drying (Mrs. H.).**—The rusty specks on the leaves appear to be dried resinous matter that has exuded from the cells and would naturally cause the foliage to wither. In the absence of any information as to the conditions under which the tree is grown we are not able to account for the peculiar state of the leaves. You do not say whether this is in a pot or planted out under glass or in the open air. This *Eucalyptus* produces more elongated and less glaucous leaves after being grown a few years, and this appears to be one of them, but it is in such a dried and imperfect state that we cannot determine the point. The large glaucous leaves produced during the early life of the tree are arranged with their upper surfaces to the sky, the lower to the earth; but the leaves that are produced afterwards are arranged more or less with their edges in those directions, and have a drooping and less cheerful appearance than the others. If you would like to give some further particulars, and send other specimens, we will readily give our attention to the matter.

**Camellias and Rhododendrons (J. R. W.).**—Planted in suitable soil, containing little or no lime, Camellias would certainly succeed well in an unheated house with a heavy roof facing the south, proper cultural attention being accorded the plants. In all probability such greenhouse Rhododendrons as *R. fragrantissimum*, *R. ciliatum*, *R. formosum*, and Countess of Haddington would also succeed, taking care not to accelerate early growth by keeping the house unduly close in autumn and during mild weather in winter, or the tender shoots might be cut by frost in the spring. Very much, however, depends on the district in which you are situated, there being nothing in your letter to indicate whether you reside in the cold north or sunny south.

**Eucharises—Tomatoes—Roses (W. W.).**—We should first establish the Eucharises in pots, then when quite healthy, plant them out in the bed over the hot-water pipes. We know of beds of Eucharises which have been furnished in that way and the plants now afford fine blooms abundantly. The Tomatoes you name are good, all of them giving satisfaction to different cultivators. Hackwood Park Prolific does not always set fruit well from the first formed flowers. Roses ought to do very well in the manner you propose, but we do not see the urgent necessity for trellises. They are well grown in the natural bush form for market purposes. We have heard the second variety you name is not a particular favourite in the London market, Niphetos and Madame Falcot being perhaps more largely grown for the sale of expanding buds than any others. The others we should not plant in large numbers at the first, but experimentally, increasing them if they promise to answer your purpose.

**Tuberose Flowers a Second Year (Tuberose).**—If you wish to try it, though we do not think it worth while, you will need to keep the plants in a

light airy position in the greenhouse and duly supplied with water until the foliage begins to turn yellow, when water should be gradually withheld. The roots will be so reduced in size as to require at least a year's growth before they will flower again, and then unless the culture has been superior you will not obtain blooms by any means equal to those from well-selected imported roots, whether they be Italian, American, or African. They are not in our opinion worth keeping for blooming a second time, especially as fine imported bulbs can now be purchased so cheaply.

**Petroleum for Dressing Vines and Peaches (Omega).**—Petroleum is not safe to use as a dressing in the usual manner with a brush to Vines or Peaches from the difficulty of keeping it mixed whilst the operation is being performed, for to mix with water it requires to be agitated—kept briskly stirred—which requires two persons, one to keep stirring the fluids while the other applies the mixture. If you, however, intend to use it as a wash and syringe it on, which is the best means of applying it, dissolve half a pound of softsoap in 3 gallons of boiling water, and when cooled to 120° add a quarter of a pint of petroleum and stir well with a broom handle until the petroleum is mixed with the soapy solution, and stir briskly whilst another person applies it to the Vines or Peach trees, being careful to wet them thoroughly in every part, on which the efficacy of this and all insecticides greatly depends. If there has been a great infection of insects repeat before the buds begin to swell, it being particularly efficacious against scale, mealy bug, indeed all insects, but requires to be used with care and judgment. If there be plants under the Vines they should be removed whilst the petroleum is being used, and it must not be used after the buds commence swelling.

**Compost for Vines (Idem).**—The top 3 or 4 inches of a pasture where the soil is medium-textured, light rather than heavy, taken off with its turf, should form the staple of the compost, or a ninth—i.e., ninebarrowloads or cartloads to one of old mortar rubbish, and if the loam is deficient of sand add one of river sand, half a load of charred refuse or wood ashes, and half of charcoal; but the sand may not be necessary, and if the loam is not from a calcareous formation add a load of calcined oyster shells, and under any circumstances a sprinkling of crushed bones, which should not be less than half, nor more than a load. The less calcareous the loam the more bones may be used. Mix all well together, the loam being broken up roughly, and turn the heap over again, so as to insure the thorough incorporation of the mass. Such a compost will grow Grapes to perfection, and last a lifetime with proper surface dressing and good management generally.

**Culture of *Pancratium fragrans* (R.S.).**—This beautiful plant requires a rather high temperature and a moist shady position; a stove heat of 70° in summer and 60° in winter should be the minimum. Your plants should be shifted as soon as they fill their pots with roots. When the specimens are as large as required they should only be potted every four years. Employ a compost of two parts fibry loam, one part charcoal, and one part silver sand and sheep droppings. The loam must be broken into pieces about the size of pigeon's eggs, the charcoal the same; when all has been turned two or three times it should then be run through a half-inch riddle, and what remains in the riddle place in the pots. In potting the soil should be rammed very firmly. In the stove they should be close to the glass, but shaded from the direct rays of the sun, and they should receive a bountiful supply of water in the summer time both from the watering can and syringe. Even during the winter the syringe must be more freely employed than for most stove plants, particularly so if the stove in which they are placed is not furnished with vapour appliances. They can be placed in a cool conservatory when in flower, and supplied with a little weak liquid manure; it prolongs their flowering season, and also imparts a much finer waxy appearance to the flowers—moreover, they last much longer in a cut state when subjected to this treatment.

**Propagating Hardy Ferns from Spores (G. W.).**—Choose a pot which a bellglass will just fit within the rim, place a large crock over the hole, half fill the pot with smaller pieces, and on them place half an inch of moss; then fill the pot to the rim with the following mixture—viz., sandstone broken in all sizes from that of a grain to a hazel nut, sandy fibrous peat and yellow fibrous loam, of each equal parts, adding to the whole one-sixth of silver sand. Put over the surface a very small quantity of sifted soil, and make it firm by pressing it with the hand. Put on the bellglass, and if it fit closely on the soil it is all right. Remove it, and stand the pot in a pan in a rather shady but not dark part of the greenhouse, for what is wanted is a diffused though not a strong light. Give a good watering all over the surface through a fine-rosed watering pot, filling the pan with water. Now take the frond with the spore cases open, and, holding it over the pot, rub it with the hand on the under side, and a kind of brown or yellow dust will fall on the soil. You may scrape the spore cases from the back of the fronds, but if the dust fall so as to make the soil brown or yellow it is enough. Press the surface gently with the hand and put on the bellglass, taking care that it touch the soil all round. Keep the pan or saucer full of water, and give none on the surface except it become dry, which it never ought to do, nor will it if sufficiently shaded and the saucer be kept full of water. When the surface becomes green tilt the bellglass a little on one side at night, and as the soil becomes greener tilt it higher, giving a gentle watering now and then to keep the surface from becoming dry. When the plants have made two or three fronds gradually remove the bellglass, and pot off the Ferns when they can be handled safely. The pots may be placed in a pit or a shaded position in a greenhouse.

**Camellias not Expanding (Inquirer).**—We submitted the specimen you sent to a skilful cultivator of Camellias who has the charge of a very large and superior collection of plants, and the following are his remarks on the subject—"It is difficult to ascertain the cause of Camellia buds falling without knowing minutely the circumstances under which the plant is treated. The cause may be simple and brought about by the neglect of some small point in culture, or it may be a natural characteristic of the variety which the utmost care and best cultivation cannot remedy. The thick round-budded varieties, such as the one sent, are far more liable to fail than those with sharper-pointed buds. Camellias such as Countess of Derby, Marguerite Guillon, and others that are similar in the bud often cast off the buds when they commence unfolding, even when the plants appear in the best possible health. Varieties that are at all subject to this, and receive even a slight check, not unfrequently cast their buds, when more reliable kinds would not be affected by any such cause. The slightest check through dryness at the

root, a very dry atmosphere caused by sharp firing during frost, or when firing has to be resorted to too quickly, excites them, and in consequence causes a number of buds to fall. One of the surest causes of failure was suggested last week—viz., not thinning out buds. Plants in the best possible health, if allowed to carry every bud they set, would soon be exhausted, and a greater percentage of the buds in all probability would fall sooner or later. The number of buds a plant is capable of opening entirely depends upon the condition of the roots and the luxuriance of the plant. While the buds are swelling Camellias require more support than at any other stage, and if this is judiciously given a great number of flowers would expand which could not otherwise do so. The health of Camellias cannot always be taken from the appearance of the foliage, which in many cases appears healthy even when the roots are unsatisfactory. When in this condition the growth made is very short and weak, and more buds are set than the same variety would produce if in a robust condition. The soil about the roots in a wet, sour, unhealthy state will cause the buds to fall or decay. Again, if the young growth by any excitement advances early according to the forwardness of the buds the flowers seldom expand. Marguerite Guillon is very subject to this, as is also Weltonensis, a thick-budded white variety, very similar in the bud to the one sent."

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (W. N.).—Golden Pearmain. (W. Farrant).—1, Verulam. 2, Chaumontel. (J. A. L.).—1, Hollandbury. 2, Blenheim Pippin. 3, Not known. 4, Crimson Queening. 5, Joséphine de Malines. 6, Belmont.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (M. H. S.).—Narcissus Telamonius plenus. (T.P.C.).—Asplenium fontanum.

#### COVENT GARDEN MARKET.—FEBRUARY 3RD.

MARKET quiet, with good supplies of foreign goods.

#### PROFITABLE FARMING.

INDUSTRY, thought, thrift, are the three conditions necessary to successful farming given in a notice in the "Land Agents' Record" of the successful working of some small farms in Sussex, of which an account recently appeared in the *St. James's Gazette*. Now, we happen to know the locality well in which the said farms are situated, and we may advert to some of the doings of the farmers to show how it is they are so prosperous in a time of adversity. Before doing so attention may be called to the fact that Sussex is coming to the front as a leading agricultural county. It has long been famous for its Southdown sheep and Sussex cattle. Sussex chickens, too, command high prices in the London markets, and some idea may be had of the magnitude of the poultry business when it is stated that in spring and summer 20 tons of dead poultry are sent off by rail weekly from Heathfield station, which is the centre of the great chicken-rearing district. The business done, too, in butter and milk is by no means inconsiderable, and this is owing very much to the manner in which the county is intersected by the Brighton railway system, by means of which the farms are brought within an hour or two of London, as well as of Brighton, Eastbourne, Hastings, and Tunbridge Wells. Travellers by the early trains hear the rattle of milkcans at every little station, and we have often while waiting for our train watched with keen interest the arrival of the farm carts, some with only one milkcan, others with two or three, all brought almost without exception by the farmers themselves, whose cheery greetings and brisk energetic action was totally at variance with the aspect of men borne down to poverty by hard times.

Very little attention is given to purity of breed in cows kept solely for milk. So long as a cow yields plenty of milk it matters little of what colour, size, form, or breed it may be, and most of the cows found on small farms are cross-bred in very haphazard fashion. Undoubtedly there is room for improvement here—not from a fanciful but profitable point of view. The "small farmer" requires a cow that yields a painful of milk twice daily—a medium-sized animal, of sturdy compact habit, that will fatten quickly for the butcher when it ceases to be valuable as a milker, in order that it may be disposed of quickly and at a profit. He wants no pedigree cows, but he certainly does want animals of the class indicated. How is he to obtain them? We know no special market to which he could turn to supply his wants, nor if there were such a market would he be likely to go out of his way to it. What is wanted is a better class of dairy cows throughout the country. There has been by far too much carelessness in this as in so many other matters in which farmers have an interest. A really good cow adapted for a special purpose is too often regarded as a wonder. Surely if general attention were given to an improvement in cows so as to render them more profitable deep milkers would be the rule and not the exception. Take any herd of dairy cows—say from two or three up to a dozen—and we may find one or at most two deep milkers. The others will be found to be decidedly inferior in point of quantity of milk. That this unsatisfactory state of things is an outcome of easy-going practice is undoubtedly true, yet how can the tenant of a small farm help himself here? We know some Sussex farms a few miles distant from a railway station where butter is the staple dairy article. On such farms there is a strong infusion of Jersey blood in the herd, and it is by no means uncommon to see several pure-bred Jersey cows.

Quality takes precedence of quantity in the milk yield. Butter-making is to the fore. Good butter never has ever will lack purchasers at a profitable price to the producer, and the average price throughout the year for a really first-class article is about 1s. 6d. per lb. But to produce first-class butter we must have first of all a clever dairy-woman, and next a well-managed herd of cows selected specially for the purpose. The milk farmer may, and in point of fact does, use brewers' grains, green Maize, cattle Cabbage, Thousand-headed Kale, and roots without hesitation. Any article of diet calculated to promote and sustain a full and abundant flow of milk is good for his purpose, but the butter farmer having regard to delicacy of flavour in it must take especial care in feeding. He must eschew Turnips, Cabbage must be used with caution, and even green Maize can only be used freely when quite young. Everything at all likely to impart an unpleasant flavour to the butter must be kept from the cows.

Of really "safe" articles of food we may mention Rye Grass, Clover, Tares, Trifolium, Sainfoin, the best meadow hay, Carrots, Mangold Wurtzel, bran, and crushed Oats. Cabbage, Thousand-headed Kale, green Maize, and silage may be used in moderation. But no oilcake should be given to cows; they do not require it. It neither enriches the quality nor does it increase the quantity of the milk. We make special mention of this because of the reckless advice to give oilcake to cows so often seen in farming papers. Although we have wandered somewhat from the special doings of Surrey farmers, yet we have not forgotten either profitable or practical farmer, and we shall return to the subject next week.

#### WORK ON THE HOME FARM.

During the prevalence of severe weather, when work on the land is practically at a standstill, the value of horse gear as a motive power becomes fully understood; but such gear should always have a roof over it so that the horses may have shelter. Then we can get on with our chaffing, pulping, grinding, pumping, and, in fact, all the ordinary work done by agricultural machinery, instead of having the horses idle in the yards. A kibbling mill is of much value in crushing corn, so that it may be easily eaten and thoroughly digested; without it much corn is liable to be passed through the stomach undigested. There are inferior mills in the market which do the work so slowly as to be comparatively valueless. A really good kibbler crushes corn quickly, whether turned by hand or steam. We have one on a small farm which requires two men to turn it easily that on wet days turns out a large quantity of corn crushed ready for consumption, and we prefer so finding employment for the men rather than run up grinding accounts at a miller's. The pastures have been covered so deeply with snow that we have had to maintain the sheep entirely on dry food and roots. With several hundred ewes and some 300 hoggets to feed we have heavy demands made upon our stores just now. Pea straw, hay, mixed chaff of hay and Barley straw well salted, crushed corn and cake, with a few roots, afford enough variety, and the sheep are in excellent condition. The last batch of old draught ewes were sold about a week ago. We purchased these ewes in autumn at an average price of 25s. apiece, and they realised an average of 45s. apiece, some going as high as 49s. This has been a profitable affair, much good having been done to the land by folding; but the remarkable improvement in the condition of these sheep is doubtless owing to lodge shelter, and to our practice of putting them in a snug yard in inclement weather. We mention this matter as one of the trifles which contribute to success in farming, and we may add that our speculation in purchasing pigs in large numbers to consume inferior corn answers well. Pigs bought in a few weeks ago at 15s. 6d. each are now being sold at 36s. 6d.—not all at once, but as they reach a certain standard of excellence. Plump little porkers they are, and we have the satisfaction of knowing that our discoloured Barley makes good pork, and is profitable to us.

#### REVIEW OF BOOK.

*Permanent and Temporary Pastures.* By MARTIN J. SUTTON. London: Hamilton, Adams & Co., Paternoster Row, 1886.

An exhaustive practical work upon pastures, bringing the subject well up to date, giving the latest information upon the best Grasses and Clovers, with particulars of ensilage, has been urgently needed, and it is therefore with especial pleasure we welcome the admirable production now before us. Some time ago Mr. Martin Hope Sutton, the founder of the Reading firm, contributed an essay on the subject of "Permanent Pastures" to the *Journal of the Royal Agricultural Society* (vol. xxii., part ii.), which was subsequently republished in pamphlet form, when it ran through eleven editions. In 1880 Mr. Martin J. Sutton undertook at his father's request the revision and enlargement of the essay, and in

the improved form two other editions were disposed of, numbering in all 20,000 copies, as we are informed in the preface to the present work. As the subject has assumed so much importance in recent years, it was thought that "a more comprehensive treatment" should be afforded it than could be done in a pamphlet, and the result has been the production of the work under notice. In the preparation of this Mr. M. J. Sutton acknowledges the assistance of Mr. W. Carruthers, Sir J. B. Lawes, Bart., Dr. J. H. Gilbert, Dr. Maxwell T. Masters, Mr. F. G. Baker, Dr. J. A. Voelcker, and others in several departments of the book, whose work gives it most valuable scientific and practical support.

The book comprises 121 pages of text, dealing with principal practical operations connected with Grass land, chapters being devoted to "The Extension of Pastures," "The Drainage of Grass Land," and "Cultural Preparations." An important department is that appropriated to "The Selection of Grasses and Clovers," in which are given full instructions respecting the uses and requirements of the leading species and varieties employed for pastures, a large amount of valuable information being conveyed in these pages. Then follow chapters on "Sowing Grass Seeds," "The Management of New and Old Pastures," "Hints on Haymaking and Grazing," "Ensilage," "Breaking up Old Grass Land," and "Temporary Pastures."

The value of the work is greatly increased by the addition of twenty-three beautifully executed chromo-lithographs representing the principal pasture Grasses and Clovers. For life-like accuracy of detail we have seen none to surpass and few to equal them. They are accompanied, with two or three exceptions, by botanical descriptions and analyses of the Grasses, both dried and in a fresh state, showing at a glance their relative importance as fodder.

The book is printed in bold type, on excellent paper, is neatly bound in dark cloth, and will form a useful addition to any farmer's library.

#### OUR LETTER BOX.

**Potatoes as Food for Cows (R. H.).**—Potatoes are not to be regarded as suitable food for milch cows, either to improve the quantity or quality of the milk. They should never be used in a raw state; cooked, ponded into a mass, with the addition of enough salt to render them palatable, they might be used in moderation, but we cannot recommend such an article of diet for cows. Our own plan is to have Potatoes cooked and given to pigs with skimmed milk and butter milk. Pigs so fed grow fast, and fatten so quickly that they require no corn. Whenever there is a dairy for butter-making enough pigs should be kept to consume the stale milk. If you have not tried a plan that is so clearly based upon the principle of sound economy, pray do so, and you will no longer be at a loss how to turn your surplus Potatoes to profitable account. We regret that a little delay has occurred in the publication of this reply.

**Sheep with Swollen Lips (J. M.).**—Your sheep are suffering from blain, or gloss anthrax. It is probably owing to the rarity of this disease that the cause of it is not always clearly understood. In your flock it is probably owing to an undue amount of exposure to cold and wet. The remedy is, to put them at once into a warm dry fold, and to keep them there; if you can spare them a clean well littered yard and lodge so much the better. Open the abscesses with a lancet to let out the humour, wash the swollen parts and the mouth with warm water, and afterwards apply a solution of chloride of lime, a drachm to a pint of water. Repeat this once or twice daily, as long as may be necessary. In severe cases there will be much debility, and the animals should have a liberal diet of oatmeal gruel; all of them should have plenty of dry food in troughs, consisting of hay, chaff, crushed oats, bran, and Waterloo round cake also crushed. A few minced roots of Mangolds, Swedes and Carrots may be mixed with this food advantageously. If any of the sheep show loss of appetite a tonic given daily of a drachm of powdered Gentian root and half a drachm of powdered ginger in a little water does much good.

#### METEOROLOGICAL OBSERVATIONS.

### THE NURSERY AND SEED TRADE ASSOCIATION

**W**E last week referred to the annual meeting of this Association, the particulars of which did not reach us in time for insertion. From the Annual Report, which was read and adopted, it appeared that in 1884 it was proposed to wind up the Association, as the principal members had withdrawn their support in consequence of the want of energy on the part of the executive; but as several members were of opinion that an Association was a necessity to the trades, it was decided to resuscitate it, and to amend the Articles of Association, enabling members to join in January or July of each year, and that the members should give mutual information to each other through the Secretary concerning the stability of persons with whom they had business transactions, and thereby obtain reliable information which could not be obtained through the channels of ordinary Trade Protection Societies; and that the operations of the Association since its resuscitation had been very satisfactory, and the Association was considered to be on a satisfactory basis, and was being energetically worked, and many foreign members of the trade who sent goods to the United Kingdom had availed themselves of the advantages afforded by the Association. The report also showed that the Secretary and Solicitor had received and paid over to the members debts to the amount of £1276 6s. 10d., which they had treated as bad, but afforded the officers of the Association an opportunity to recover, and this amount had been paid to the members without costs, excepting a small commission. The balance sheet which was read was also very satisfactory, and a balance of £48 7s. 5d. was carried forward to the present year.

No more conclusive evidence of the usefulness of the Association could well be afforded than the above record of its work during the past year; and it appears to us that it would only be a mere matter of prudence for nurserymen and seedsmen generally to take advantage of the facilities that the Association offers in the conduct of business. The remarks of the different speakers at the meeting prove the necessity of co-operation on the lines indicated in the satisfactory conduct of a great industry; and it is abundantly evident that there has been a lack of enterprise and effort somewhere, or why the suggestion to "wind up" an Association which, under sound and energetic management, is calculated to be of wide benefit to its members? In the event of a possible failure, or the existence of circumstances of an undesirable character, it is only natural that an endeavour should be made to find a scapegoat. In this instance the horticultural papers have "not stood by the nurserymen as they ought." In advocating the claims of this particular Association the "papers" have not perhaps taken a prominent share. But why is this? We can speak for ourselves, and say that we have never hitherto had a "report" of the Association sent to us for publication, and have never been requested to direct attention to the existence of the organisation; but, on the contrary, we have had the publications of the Association handed to us privately for

private perusal alone. It is not in this way the claims of an Association can be advanced in the most effectual manner. There cannot be a doubt that the interests of trade horticulturists may be far more adequately maintained by organisation than isolated individual action on the various points to which reference was made at the meeting, and we shall be a little surprised if the Association in question does not become more popular, and its influence and usefulness be materially increased if more prominent attention is directed to the facilities it offers to its supporters.

As intimated last week, Mr. N. N. Sherwood, the President, took the chair at the annual meeting. Mr. Harrison of Leicester, in proposing the toast of the officers and Committee, referred in detail to the report, and thought the executive had in a short time done wonders. They had rescued out of the fire the burning brand and saved the Association from collapsing, and the condition in which it had been now brought forward was most satisfactory. Mr. A. H. Clarke, the Treasurer, in responding, referred to the state in which the Association was allowed to drift, and that when the Committee met there was an *arrière pensée* in their minds that it should not be allowed to break up, but should do all in their power to resuscitate it and make it a success; but as a good deal had had to be done the Committee had worked very hard to get the Association into its present shape. He asked those who were not on the Committee to wake the Committee up if necessary, and it would be found that if they fell short in any respect they would answer to the whip.

Mr. William Paul, who also responded on behalf of the Committee, thought that too much praise could not be bestowed upon the Solicitor and the Secretary for what they had done to resuscitate the Association; but although it had done a great deal in the way of giving status reports and collecting debts, that was only a small part of what the Association ought to accomplish. He thought more ought to be done for the purpose of uniting the members of the nursery and seed trades. Singly their power was small, but united it would prove for the good of both. There was a great number of intelligent people in the trades. Horticultural periodicals were now represented by nine weekly papers, besides those issued monthly; but these did not exercise the influence they might if the nurserymen and seedsmen were a more united body, in which case they might retain their rights, which they were not then doing. The speaker referred particularly to the question of rates and income tax, and stated that nurserymen were paying far more than they ought to be called upon to pay, and instanced this by what occurred on a re-valuation of his parish being made for the purpose of rating, on which occasion he (the speaker) appealed to the Quarter Sessions and succeeded in reducing the amount of rating by one-half. If this question had been taken up by such an Association as the present one a principle would have been established which would have affected nurserymen all over the country, but as it was only an isolated case it could not be utilised on behalf of others. He also referred to the question of railway rates, which required consideration, and which could only be efficiently dealt with by a large body engaged in the nursery and seed trades with any hope of bringing the same to a successful issue.

Speaking as a contributor to the horticultural papers, he was of opinion the latter had not stood by the nurserymen as they ought to, but he thought if they made their power felt as a body not only they, but the trade itself, would find it to be of great service. He referred to the rules of the Royal Horticultural Society, which precluded nurserymen from being on the Council, and thought that if this matter were properly represented by an Association of nurserymen such as the present an alteration would be effected.

Mr. Hooper proposed the health of Mr. Butcher, the Solicitor to the Association, and in responding that gentleman pointed out that the Articles of the Association were sufficiently large to enable the matters referred to by Mr. Paul being taken up by the Association, and that if those engaged in the production of seeds and flowers thoroughly united themselves as a body they would be sufficiently strong to have a voice in the Chamber of Commerce upon the matters considered by that body. He advocated legislation in the interests of nurserymen, giving them the right to demand compensation on expiration of tenancy from their landlords or succeeding tenants in respect of buildings and improvements to the land.

Mr. Veitch proposed "Success to the Nursery and Seed Trade Association," to which Mr. Sherwood, the President, replied in suitable terms. Other toasts followed, and a very successful meeting was brought to a close.

Now that our co-operation has been requested we readily give prominence to the claims of the Association in question to extended support, as we yield to none in our desire to see all the branches of trade in connection with horticulture in a prosperous condition.

### TREE OR PERPETUAL FLOWERING CARNATIONS.

In the garden few flowers are more cherished than the Carnation; it is always in request for its charming fragrance, and never more than during this dull season. To have them in winter requires only a favourable position outdoors during the summer

and autumn, a little attention in sticking and tying, and needful supplies of water. They are of easy culture, requiring no more skill than is needful to grow softwooded plants. To insure good plants the chief thing is to propagate early, from the beginning of February to early March, affording plants from cuttings by November that will bloom until those in the open ground come in. The short stubby side shoots are the best for cuttings, slipping them off and merely making any raggedness at the base smooth with a sharp knife, or if slipped off carefully this is not necessary. They should be dibbed round the sides of pots inside, varying with the number of cuttings, or most conveniently into 5-inch pots, leaving them about an inch apart. Employ fine soil—loam three parts, one part leaf soil, and a similar proportion of sand, with a half-inch layer of silver sand on the top of the soil. Drainage may occupy one-third the depth of the pots. Water after to settle the sand about the cuttings, and plunge in a gentle bottom heat of 70° to 75°, and top heat of between 55° and 65°, but the lower one is best, as it is rooting not top growth that is sought, for the sturdier the plants are kept the better. Place a bellglass over the pots with the edges resting on inverted 3-inch pots, so that evaporation will be to some extent lessened, and they will get sufficient air to prevent damping.

When the cuttings are rooted remove the cover and stand the plants on shelves near the glass, but in the same temperature until the pots are fairly filled with roots, and then pot singly, the smaller ones into small 60's, and the strongest in the larger 60's. The compost should consist of good turfy yellow loam three parts, a part in equal proportions of well-decayed manure, and about a sixth of sharp or river sand. Pot firmly, but use the fingers only. The plants after potting may be returned to the forcing or warm house and placed near the glass, the most suitable temperature being 50° to 55° by artificial means. In this they will make steady growth, and there they may remain until they are moved to cold frames about the middle of April, having protection at night by mats in frosty weather, and gradually harden them off so as to have them fit for standing outdoors by the middle of May. Repot the plants as the roots advance, not allowing them to become rootbound before doing so, at the same time the pots should be filled with roots. Give the final potting early in July at the latest, and preferably early in June. Use 5 or 6-inch pots for the smaller plants and weaker-growing varieties, and 7 or 8-inch pots for the largest and most robust sorts. A neat stick with the main shoot tied to it and the side shoots looped toward it so as to form a sort of pyramidal specimen is all that is needed in the way of training. Afford a sunny position outdoors, open, but sheltered from winds, and a bed of ashes, in which the pots may be partially plunged. After the pots are filled with roots liquid manure may be given at every alternate watering. By October there will be plenty of flower buds in an advanced state, and the plants should be transferred to a low, light, well ventilated structure with a temperature of 50° by artificial means, when they will give an abundance of blooms successional through the winter. They do not like damp, and gentle heat is necessary to enable them to open their buds in winter. It is deficiency of heat that causes the Tree Carnation to be considered non-winter-flowering by some growers.

Those wanting plenty of blooms in spring should insert cuttings early in March. Most people have a hotbed then, and this will answer, only it must not be too warm or the cuttings will be drawn before they are well rooted. When sufficiently rooted remove them to a greenhouse, and being hardened to that temperature pot them and grow them on in cold frames until May. The summer treatment is the same, only the plants may have their largest pots as late as early August, and in autumn or before November they should be placed in a light airy greenhouse. Supply water carefully, being cautious not to give too much. Freely ventilate on all favourable occasions, as this will harden the growths, and on that the flowering in a great measure depends. From the middle of February onwards weak liquid manure once a week will help the plants greatly.

Another plan is to turn the plants outdoors as soon as the flowering is over, and layer the strong growths in 4-inch pots. These layers will be well rooted in about six weeks, when they are detached from the parent and stood in the shade or under a north wall for a few days, in which position they feel no check and make roots rapidly. The pots being well filled with roots, shift the plants into pots a couple of inches larger in diameter, but any plants layered in 3-inch pots should only have the 5 inch size. Stand them in an open situation, and house by or before November. Plants raised in this way are very dwarf, and give a number of useful flowers in spring and early summer, but I do not find them so floriferous as plants raised by the two previously named methods.

A fourth plan, and one that with the raising of plants from layers, commends itself to those not having only a handlight or cold frame and a greenhouse. This is to insert cuttings under handlights as soon as the flowering is over, or about the middle of July; placing in about 3 inches depth of fine soil and a surfacing of silver sand. The cuttings should be cut immediately below a joint and have leaves removed from it with a sharp knife, and if the cuttings have one joint and the centre leaves it is sufficient. Insert them up to the centres, but not so as to bury the centres, and press the soil firmly, giving a gentle watering, and the handlight being put on keep them close and shaded from sun. They will root slowly but surely, and in autumn can be lifted and placed singly in 3-inch pots, in which they may be wintered in cold frames. In spring they should be repotted and have their largest pots by July. Six, seven, or eight-inch pots will not be too large. Any disposition to flower must be at once checked prior and up to the beginning of August, after which allow all to advance that shows. Although we get large plants by this method they are not proportionately as floriferous as the smaller and early-raised plants; indeed, it is the starting of young plants or raising them early which gives them their tendency for early or winter flowering, for if treated as border plants they do not flower until the ordinary time in summer, but unlike the show varieties they continue flowering outdoors until a late period, and on that account are valuable, especially if grown in a sheltered situation.

I have tried, but do not recommend keeping the plants after the first year, hence young plants should be raised annually, as affording the finest flowers in greater profusion. Insects are not much trouble; indeed, the only ones attacking these plants severely are aphides, which soon succumb to fumigation or when outdoors to syringing or dipping in tobacco water or some approved insecticide.

The varieties are becoming very numerous, but I consider the following some of the best:—*Scarlet*—Field Marshal, M. Baldwin, Duke of Albany, and Worthington Smith. *Red*—Lueifer, Leon Lambertye, and Zouave. *Crimson*—Mrs. Keen, Sir Evelyn Wood, and The Moor. *Purple*—Gladiateur, Duke of Wellington, and Ruby. *Maroon*—Rubens, Phoenix, and Brunette. *Rose*—Rose Perfection, Madame Alégatière, and Seraph. *Pink*—Miss Jolliffe, Laura, and Le Favori. *Yellow*—Mrs. George Hawtry, Andalusia, and Pride of Penshurst. *White*—Snowball, Princess Stephanie, and The Queen. *Fancy Varieties*—Thomas Wallis, scarlet, striped dark red; Whipper-in, scarlet, dark stripes; Enchantress, pink, flaked purple; Iona, rose, flaked and spotted carmine; Memnon, buff, striped rose and orange; Volunteer, scarlet, striped maroon; Hamlet, buff, striped rose; Cassandra, buff, edged scarlet (Picotee), and Sunbeam, creamy white, edged pink (Picotee).

I wish to close with an especial note on Souvenir de la Malmaison, blush white, and the pink form (syn. Lady Middleton) of that grand variety—viz., those wishing to have a quantity of flowers to send to town in May and early June should have a house full of these, they coming in most acceptable, and are a relief from the stereotyped Gardenia.—G. ABBEY.

#### LIME FOR VINE BORDERS—ANALYSIS OF SOIL.

THE communication by "A. L. G.," on page 62, may be attributed to one of two causes—either that he is anxious to air his knowledge of elementary chemistry, or for gaining information. If the former, I wonder that he did not tender us more of his knowledge on the subject of liming, or state definitely his reasons for differing from "A Thinker" on the Gros Colman question. If the latter, his method of eliciting information may not be one of the best.

I should be very sorry to infer that "A. L. G." tried to misrepresent what I wrote on pages 37 and 38, but the least that can be said is that his remarks on the subject, and quotations from "Warrington's Chemistry of the Farm," will serve to confuse those for whom my article was penned. Your correspondent might not allow his Vines to fail to colour through deficiency of lime in the borders, neither have I advised such a course, but there are thousands who grow a house or more of Vines who do not possess either a knowledge of elementary or analytical chemistry. The chief soil, of which many Vine borders are composed naturally contained no lime, and the quantity incorporated when the border was first made would sooner or later fail to prove beneficial to the Vines; on the contrary, in a few years this substance would become deficient, and the crops prove unsatisfactory. My object was to help those, if possible, who have not, through no fault of theirs perhaps, the same amount of knowledge that "A. L. G." appears to possess. Many, and I believe there are many, may be labouring to colour their Grapes

who do not know that the cause of their failure is due to the cause I tried to point out.

I do not possess "Warrington's Chemistry of the Farm," but expect that the quotations given from it apply largely to agricultural soils, and what is the difference between these and the soil of a Vine border? What is the per-centage of humus contained in the former compared with that in the latter? If the analysis of the ashes formed by burning the wood of Vines is any guide, it cannot well be disputed that lime is an indispensable article of food for them, as well as many other plants. If this is the case, then lime can be applied annually or periodically, as I explained, with beneficial results to them. It is indeed questionable if agricultural soils contain one-third, or even one-fourth, the humus of a Vine border. It is a very common practice to apply heavy dressings of manure annually, and of what benefit will this prove to the Vines when there is already abundance in the border that they cannot take up or use? To add animal or vegetable matter to a border of this description is only adding fuel to the fire, and this is being done every year. But if lime was applied, would it not set some of this mass of food that is lying dormant at liberty, so that it could be assimilated by the Vines for their support and that of the crop? I think it will clearly be seen that I only advised a certain percentage of lime to be applied annually, and at the same time as much manure as would restore the amount of humus extracted or diminished. I am aware that it would be simply madness to apply lime to a Vine border already poor and containing practically little or no humus. Its power of decomposing fibre and other vegetable matter quickly had not been overlooked; on the contrary, I was aware of this, and for this reason I advised its use so that the fibry loam and manure applied with it annually could soon be reduced to such a condition that Vines could utilise it for food in the manner they most desired.

Now to turn to the kitchen garden to which I alluded, not a mere Cabbage bed, which had been heavily manured, and was so full of humus that plants would not grow in it, either Cabbages or any of the Brassicas. Two previous gardeners had condemned this garden as worn out, and they appealed for a new one. The dressing of lime brought this garden into a fertile state; not a mere sprinkling of lime, but it was applied at the rate of 250 to 300 bushels per acre, if that amount was not exceeded, I cannot now tell exactly without looking back for vouchers, which would give me considerable trouble. This was applied seven and eight years ago, and lime has since been applied, in fact, a little annually, but not in such large quantities, and the most beneficial results follow its application for the productiveness of the garden is increased by its agency. The amount of humus in the best of agricultural soils cannot be above one-third what it is in highly cultivated kitchen gardens, neither is half the produce taken from the land. From my garden I require and get two crops from the great part of it annually, and when this is done there is naturally something taken out of the soil, and I believe in putting something in. By this means, even if lime is freely and periodically applied, the fertility of the ground is not destroyed. It would be, I readily admit, if we applied lime and took all out of the soil we could get, and put nothing back again. I am afraid there is much agricultural land exhausted of nearly all the humus it contained without the application of lime to assist. On the best managed farms what is the amount of manure applied in comparison to what is the case in a garden, and therefore it is naturally less rich in humus. The renovation of the garden in question and its fertile state I attribute to a free and judicious use of lime. With the exception of growing Parsley and Carrots, no one need desire a better piece of land.

I noticed someone asking in the Journal what to do to prevent "clubbing." My advice is to give a thorough good dressing of hot lime a short time before the ground has to be cropped in spring. This proved an effectual cure in the garden to which allusion has been made. The best way of applying it is to dig deeply or trench the ground, and then spread it on the surface after it has fallen to dust, then dig it in. If the ground has been heavily manured none need be applied unless on the surface of the soil to be cast towards the bottom of the trench as the operation of trenching or digging proceeds.—WM. BARDNEY.

INDIVIDUAL.—Surely for a writer who freely criticises others "Thinker" is too sensitive, and I am as much surprised as sorry that he should for one moment considered that my story was told as in any way applicable to him. I merely told it by the way, and if he reflects for a moment it will surely strike him that if I meant to imply that he corresponded to the hurly "Liberator," I must have compared my excellent friend, Harrison Weir, to the Dublin "fish-fag!" It could have no point at all in reference to the matter, for the point was that Dan's antagonist no more understood the

meaning of "individual" than if, in reference to the element from whence her wares were taken, he had called her a "palufothboios thalasse." I must utterly disclaim being regarded as a "facetious man;" on the contrary, I am regarded as rather a staid individual, who rolishes a joke even when told against himself.—D., Deal.

### SCUTELLARIA MACRANTHA.

THOUGH less showy perhaps than some other of the Lipworts, many of the Skull-caps are very ornamental plants, and none more so than the *Scutellaria macrantha* represented in fig. 18.

This is a native of Eastern Asia, and appears to be widely spread extending, according to Sir William Hooker, to the great wall of China where it was detected by Sir George Staunton. As might have been anticipated, it is perfectly hardy and of easy cultivation and increase. It is an herbaceous perennial, scarcely exceeding 1 foot in height, with angular, branching stems, and opposite, entire, lance-shaped leaves, and forming when sufficiently strong a spreading bushy tuft. The very handsome purple flowers are produced in long terminal spikes, and are larger

Fig. 18.—*Scutellaria macrantha*.

than those of any other species known to us. The plant seeds freely, and may be readily increased by these means, as well as by division of the roots, or by cuttings under a glass, either in the border or frame. Seedlings usually flower the first season if sown early, and should be transplanted from the seed pan while young, as they will suffer less from removal than at a more advanced state of their growth, when their tap-like root is more developed.

With regard to soil, a mixture of good loam and decayed leaves or manure appears to best suit this plant, though it will probably flourish in any good garden soil; for many hardy plants, like individuals, possess the happy faculty of adapting themselves to situations of diverse character, provided that they are not of too extreme a nature.

It disappears so entirely during the winter months that it is advisable to mark its place in the border by a label of some description, for much injury is often done to plants of a similar character when the borders are dressed in spring, from ignorance of the precise locality of their roots.

When first introduced this plant was recommended by Sir W. J. Hooker as a desirable one for planting in masses, and now that its seeds are readily procurable at a reasonable rate, its employment for this purpose may be fairly made the subject of experiment, as its flowering season is of considerable duration. The effect would probably be enhanced by planting it in association with the yellow-flowered *S. orientalis*.

talís, a plant of similar habit and height. It must, however, be conceded that neither of these plants can vie in brilliancy with the plants usually employed in bedding, and their proper place is perhaps the front row of the mixed border.—W. T.

## HINTS ON THE CULTIVATION OF HARDY FRUIT TREES.

AT the last monthly meeting of the Lee, Lewisham, and Blackheath Horticultural Society, held on January 29th in the Working Men's Institute, Old Road, Lee, Mr. Pavey, gardener to W. Watkins, Esq. (of the firm of Howcroft & Watkins, the well-known London seedsmen), Eltham Road, Lee, read an excellent paper entitled "A few Hints on the Cultivation of Hardy Fruit Trees," in which he very ably described the various methods of planting, training, and pruning, and the best modes of destroying insects, &c., injurious to fruit trees.

He dealt with the important subject of planting in a thoroughly exhaustive manner, laying particular stress on the necessity of providing good drainage for the planting stations, especially on cold, damp, and heavy subsoils. To the absence of good drainage he attributed the chief causes of failure in growing fruit in many gardens, rightly stating that to this cause was due the existence of canker, especially among Apple trees. He advocated the thorough preparation of the planting stations by giving ample space to each tree, and the great importance of forming in the case of clay subsoils a good hard bottom by means of concrete, thereby preventing the formation of tap roots and the roots generally from penetrating into an uncongenial subsoil. Mr. Pavey had many years ago experienced great difficulty in cultivating fruit trees in the garden of which he still had charge owing to the uncongenial character of the soil, but after he had set to work and prepared new stations on the principles recommended no difficulty occurred, seasons permitting, in obtaining excellent crops of fruit with fine healthy and vigorous trees.

The distinction between the positions (culturally) of market and private growers was pointed out, the former having the advantage of pitching their tent, so to speak, on just the right kind of land suitable for fruit-growing; hence, as a general rule, market growers were able to produce greater crops than private growers; whereas the latter have to be content with whatever position and soil builders—suburban especially—choose to erect the houses on. Here, then, lay the necessity of adopting such artificial means of assistance as would conduce to ultimate success.

Another important point mentioned was the advisability of planting and growing fruit trees in quarters to themselves instead of (as in the usual way) their being planted round the margins of the walks; urging as a reason for adopting this plan that when planted in quarters the blossom was better protected from injury in early spring and the roots from being interfered with during the important period of growth. On this point particularly most experienced cultivators will agree that considerable injury is often done to the roots of fruit trees during their season of growth by the unavoidable disturbing of the soil in planting and lifting vegetables when the trees are growing round the quarters of the vegetable garden. Where the proposed, and indeed often adopted, plan of growing fruit trees in quarters to themselves can be carried out it will be found highly advantageous. The kitchen garden will, perhaps, not look quite so well furnished without its marginal trees, but where it is a question of abundance of fruit in preference to effect there the quarter system should be adopted without hesitation.

Next came the important subject of summer and winter pruning. Mr. Pavey expressed his disapproval of summer pruning as generally practised, believing that the constant practice of pinching and stopping the growths had an injurious effect upon the progress of the fruit during its development. His idea is that when a tree is in full growth removing a portion of its growth seriously checks the flow of the sap, and thus prevents that healthy free circulation which is so essential, he thought, to the well-being of the tree. All that would be done by way of summer pruning to cut entirely away all weakly growing shoots, but not by any means stop the stronger-growing ones, leaving these to act as the lungs of the tree until growth had quite ceased, and then prune in the usual way. Much, however, expressed under this heading did not meet with entire approbation from some of the members present.

Root-pruning judiciously carried out was considered to be an excellent remedy for reducing gross-growing trees to a fertile state. He did not, however, advocate doing too much in this way at a time, doing one half of the tree the first and the other the second year.

Then a few interesting remarks were made on some of the insects affecting fruit trees and the best modes of eradicating them. For destroying American blight he advised 8 lbs. of soft soap to be dissolved in 4 gallons of boiling water, adding a wineglassful of paraffin, and when cool thoroughly scrubbing the affected trees with it.

Finally attention was drawn to the advisability of planting fruit trees in the shrubberies of small gardens instead of so many Almonds, Horse Chestnuts, and Hawthorns. He strongly urged the adoption of this plan on the score of utility, as not only would their blossom prove quite as effective in spring, but there would be the advantage of a good crop of fruit as well.

There is certainly no reason why a few of our hardy fruits should not be grown as recommended, because they would prove not only ornamental but useful, and this is a great desideratum in small gardens of limited dimensions. A gentleman, well known to the writer of this report, and who possesses excellent taste in landscape gardening, has often remarked how beautiful and appropriate the Apple and Pear would be grouped with other trees in our shrubberies, and this gentleman has carried it out in practice.

A discussion followed the reading of the paper, in which several of the members took part, agreeing for the most part with the principles advocated, and at its close a hearty unanimous vote of thanks was awarded to Mr. Pavey. This Society has only recently added to its sphere of usefulness and attraction these social meetings, which at present augur well for its future prosperity. Mr. Pavey only dealt with hardy fruit in the open quarters; those on walls are to form the subject of a future paper. The next paper will be read by Mr. Fox, gardener to Mrs. Penn, The Cedars, on "Forcing Strawberries."—T. W. S.

## MIDWINTER ORCHIDS AT CHELTENHAM.

AT this season of the year an array of Orchids in flower, such as I have recently seen at Mr. Cypher's nurseries in the Queen's Road, is a cheering sight. I spent an agreeable hour among these Orchids, which was rendered all the more pleasant owing to the intelligence and patience of Mr. John Cypher in carefully informing one of all the interesting particulars concerning many of them. In the new Cattleya house were numbers of *Barkerias*, which included the lovely *C. Skinneri*, with rosy purplish mauve flowers, with its broad and distinct labellum; and also *B. Lindleyana*. Amongst the *Cattleyas* are to be seen *C. Loddigesiana*; *C. Trianae*, a pale variety; and the yellow-flowered *C. Holfordi*, a very distinct *Cattleya*, carrying twenty-two flowers. Near by were *Lælia anceps Barkeri*, a very fine form; also *Lælia autumnale*, the plants of the latter are very late, which gives them additional value just now. Here they are flowering with their wonted freedom, and have fine spikes of flowers as much varied as the plants themselves. Of *Oncidium Jonesianum* three distinct forms are grown; particularly noticeable was a variety with very dark purple-chestnut spots, the upper portion of the lip spotted with crimson. There are some fine forms of the well known *Cypripedium insigne*, among which are several carrying two flowers in a scape, evidence at least of good culture. Nor must the *Cœlogynes* be omitted; these are just bursting, in fact some already open, and extremely useful they are. Conspicuous among them all is the Chatsworth variety, in which the pseudo-bulbs would appear less numerous and more widely scattered than in the type, and apart from these distinctions it invariably carries in these nurseries two spikes of flowers to each flowering pseudo bulb; if this is general with this variety it is certainly doubly valuable.

In the *Odontoglossum* house are many beautiful forms of *O. Rossi majus*, all suspended near the glass. Among the *Cypripedes* in this house were *C. insigne Maulei* and *Chantini*, the latter spotted with light violet. In this house *Lycastes* abound, some in flower, others on the wane, and numbers beside throwing up strong spikes. There also I noted the satiny flowers of *Masdevallia towarensis*, of which a profusion has been maintained since October last, but it is now nearly over. The East Indian house is bright with many flowers, the chief attraction being the many deep-coloured arching spikes of *Calanthe Veitchi*, but *Saccolabium giganteum* is handsome. Then we notice the so-called white *Dendrobium bigibbum*, *D. leucophotum*, but which somewhat resembles in the form of the inflorescence *Freesia refracta alba*, in which the flower spike having attained the maximum, a horizontal direction, on which the flowers of this *Dendrobe* are closely arranged. Other *Dendrobes* in flower are *D. bigibbum*, *D. Ainsworthi*, *D. nobile*, with *D. heterocarpum*, which are its parents, the latter very sweet, and the welcome *D. Dearii*, the most durable of all the white *Dendrobes*. The plants of *Ainsworthi*, which are many, are specially noteworthy for vigour, due in a great measure to plenty of heat, abundance of moisture, and a position close to the glass. As an instance of their progress in twelve months, I may state that a year ago each of the plants consisted in most cases of a single bulb from 2 to 3 inches long, from these have sprung some fine pseudo-bulbs, stout and massive, the longest about 1 foot, and others 6 or 7 inches. The whole of the

plants have similar growths, and two and three on each plant at the present time—a remarkable instance of cultural skill. Among other flowers are *Cypripediums biflorum* and *Spicerianum*, *Peristeria elata*, *Angraecum sesquipedale*, and *Vanda Sanderiana*, a very deep-coloured variety, just passing. There are many others in flower which space forbids to name now, and then soon will follow the *Cattleyas* and many *Dendrobies*; those I have named, however, constitute a fine display.—J. H. E.

### FARMERS AND GARDENERS.

THIS subject has been very ably discussed, but a few words for the farmers will not be out of place. If my memory does not fail me, about fifteen years ago "farming" was at its best, not by steady and sure progress, but by a great leap of prosperity which unduly stimulated not only it but every other trade, and which, as subsequent events prove, has done more harm to the country than good. Prices of agricultural produce were then very high, almost double the prices as stated by "Thinker" on page 2. Machinery was becoming largely used, thus superseding much hand labour, and men consequently rushed to the towns for higher wages. Farmers undoubtedly then made great profits, and through that cause were able to pay greater increased rents to the landlord. But tradesmen who had themselves made small fortunes saw with envy the position the farmers then held in reference to profits, and the supposed ease and pleasure of a country life. They then entered into competition with the farmers for the possession of the coveted farms. The result was that either farmers had to take increased rents or leave their farms, which of course they naturally did not like, as perhaps the farm might have been in the possession of their family for a century or two. By such means perhaps more money was paid for the land rental than it was practically worth, as subsequent events proved. Bad seasons began to follow the prosperous ones. Agricultural produce prices began to fall through the keenness of foreign competition. But to make matters worse wet seasons came in succession, thus preventing the farmer getting his crops properly harvested, and also entailed a large amount of extra labour as well as giving produce of inferior quality. Wet seasons not only affected the crops, they had undoubtedly a great deal to do with the increase of cattle disease. As it is well known, couch grass and weeds spread more in wet weather, and this accounts for the deplorable state of the land, the wet seasons preventing the farmer getting his land clean. But who did bad seasons affect first? The tradesman who had made his fortune in the town and who had taken to farming in the hope of increasing his gains; but he found that farming was not to be learnt behind the counter and succumbed, his capital soon becoming exhausted through his ignorance of farming and the high rental he paid. The experienced farmer naturally survived longer than his town competitor; but taking into account the great reduction in value of all kinds of agricultural produce, he is now in my opinion entitled to a reduction of rent which shall place him on the same footing as before rents were increased in the so-called "good old times" all over the country.

Perhaps after describing the farmer's past history we may look at the proposals which are put forward for his benefit. They have been advised to take to "market gardening;" but although it might benefit those who live near towns, I think that the present state of prices and the railway charge for carriage to market make it impossible for them to follow it with any success; and I did not see a very encouraging report of farmers who had in Essex taken to growing Onions and other vegetables, as it was stated that they had been left on the ground to rot on account of the unremunerative prices. I agree with "J. T. S." that farmers could do better if they would turn their hand to some of the smaller industries, such as the rearing of fowls in greater numbers and the larger production of eggs and butter, for I think the prices of grain will never greatly improve in the face of foreign competition. "Thinker" considers that higher cultivation in farming ought to be aimed at, and with that I thoroughly agree; but may I remind him that many farmers have had their capital washed away by the wet seasons? He also speaks of the supposed advantage they possess in being nearer home markets, but the cheapness of freightage from America and the few taxes they have to pay places both parties nearly equal. It is a known fact that grain can be brought as cheap, if not cheaper, from New York to London than it can from Cheshire to London. I think improvement would follow if British farmers were placed on an equal footing with their American cousins in reference to railway rates, and also confidence should be brought into farming, so as to encourage capital to be invested in the land; and I think local rates which press so heavily on land ought to be equitably readjusted. With fair rents and seasons like the last two we have experienced farming will come back to sure and steady prosperity we all hope for, as it is certain the position of gardeners would be improved thereby.—A. E. H.

FROM their omission in "Thinker's" opening paragraph I conclude we agree in agricultural depression being mainly due to badly cultivated land and in the "manufacture" of gardeners by premiums, bonuses, and favouritism. As he also does not say one word against gentlemen selling garden produce the difference between us is much simplified. Still it is painful to see land growing as much couch as Wheat, pastures not depastured, homesteads without tenants. Think of these things, Mr. "Thinker," and tell us if it is not in a great measure due to driving the labourer from the village to the town, and adding nothing to the soil. I do not think I need trouble your readers with any comments on paragraphs 4 and 5, as they contain nothing but an idea existing in the minds of those

fearing open competition. "Thinker" clearly believes in "fair," I in "free" trade. It is not my business to look after the assessor—to tell him I have given up growing solely for my employer's use, but as we sell some of it I wish him to make an early call. If I improve the soil and make it grow double, ought I to be assessed at a higher rate? The question is the same whether I sell or not. I do not believe in an inequality of taxation, and I do not comprehend why a house costing £1000, and let at £50 or £100 a year, should be more highly taxed as a lodging house than as a private residence; but if the house as a private residence only lets for £50 and as a lodging house at £100, it is clear which valuation it would be rated upon.

Now for your question, Mr. "Thinker." Suppose I have saved a little money and may get some land, work hard, my market-gardening experience coming in useful, and build a house, grow and sell something. I suppose I shall not be obliged to tell what is made out of it annually. If asked, I could say it is there: It cost me so much, say £50; well, it is worth £5 a year to you at 10 per cent., and he assesses me accordingly. A retired tradesman opposite has put up a conservatory costing £100, and is only rated at 5 per cent., or £5. I should grumble even at that, and what I should do if the tradesman began to sell I do not know; certainly grumble harder, and at the next assessment appeal. If a person selling the produce of the land he cultivates himself is not taxed upon the same scale as others similarly occupied there is an inequality, and if a garden which has previously been devoted to growing for home use is taxed at a less rate than that of growers for sale, then the inequality comes in again, for if the grower did not produce his own flowers, fruit, and vegetables, he must of necessity buy—that is, if he will have these he ought to pay for them, whether he produces them himself or they are grown by others and purchased by him. My contention is, that whether a man cultivates his own garden or whether it be let it should be rated at its full annual value or rental. I am not aware that there is any difference between the rating of the garden and structures in it of which I have charge than of the ground and structures in a neighbouring nursery. If a garden that hitherto has only grown sufficient for the establishment grows more and sells, I cannot see any injustice in not seeking an "early rectification" simply because the rate is as high (with a tax on the labour in addition) as land used for a like purpose in the locality.

Allotments are coming to the front. I think there is plenty of them in most parishes; at least, there was in the village where I was born. My father and grandfather had one each, and the rent was 10s. per rood, 40s. per acre. This was over forty years ago. Both had the three acres of land and the cow, and I wish every labouring man had the same. It would fix him to the soil, and it would be better for the landlord, the tenant, and others. But to stick to one thing. Allotments have been provided on every estate I have been on, east, west, north, south; and where they have been insufficient for the increased population a representation at the proper quarter has insured a sufficiency. I want to know why an allotment should be rated at a higher value than land adjoining under plough. If there is any logic in "Thinker's" reasoning it ought to be. Under deep spade cultivation and more cleanly culture it will grow double, it is worth more; Why not tax it higher? Take two allotments; of one the occupier consumes the produce, the other is cultivated to grow for sale. Why should not both be taxed alike? The first derives no profit; he gets as much as the other, but in a different way, because he grows for himself, but the other does because he sells; and ought he to suffer? The grower for himself exhibits for the most part little skill in culture, but the grower for sale must cultivate well if he seeks a balance on the right side of the ledger. Private gardens, as a rule, are very indifferently cultivated, some of them woefully neglected, and the sooner they are turned into market gardens the better for the owners, the better for the gardeners, and the better for the public. Gardeners by so doing will be "looking well and honestly after their masters' interest and their own." It is the gardener's first duty to earn his own living, and above all things give his employer confidence in him as a cultivator not afraid to compete with the market gardener, and if need be with nurserymen in the open market.

I believe that gardening for utility will assuredly supplant gardening for fancy. I do not advocate gardeners turning greengrocers and costermongers; one trade is enough for me, and that is to grow all and the best I can, selling it in the open market. The remedy for the "middleman" is simply to do your own marketing. If people will have things brought to the door they must pay for it, and if they will have credit they must be charged interest, but it does not suit—UTILITARIAN.

In this Journal for January 7th, page 2, I was a little surprised to read in "Thinker's" thoughts on the past year his reference to farmers and gardeners. If "Thinker" had ever been one year in a farm house I fancy he would have found the farmer not quite such a sluggard as he represents him to be. The farmers have pushed forward through this great depression with equally as much energy as the private or market gardeners, also there are very many farms well managed, and the land well cultivated. "Thinker" says five or six quarters of Wheat per acre should leave a living profit. I have seen six and a half quarters of Wheat per acre, and seven quarters of Barley per acre this last season, and still there is great depression. Mr. "Thinker" quotes five farmers to 1000 acre farm, where one who have farmed it and could not get a living profit. If Mr. "Thinker" could insure five or six quarters to the acre every year, and good luck with the stock, perhaps the farmer can live, but not to get a return for his capital, which ought to be recovered as well as in every other branch of industry. Now, I say he cannot insure five or six quarters per acre even on the best land in adverse

seasons. Farming, as well as gardening, is under the influence of the weather. I believe, with many others, that the times were never much worse. Has "Thinker" known Wheat to be below 28s. per quarter? I have not. If he had attended Boston Market the other week he could have seen plenty on offer, at least that was the average of the market.

The rent question "Thinker" has brought down to the lowest ebb; but what about the rates? The School Board rate is now more in many parishes than the Poor's rate was forty years back. I think he will find the rates from 60 to 80 per cent. higher than they were forty years ago. Do not these rates and the tithe tell heavily against the farmer? and can he expect the wages to be maintained as high as they were two years ago under the present depression in the agricultural districts, or the present low prices of corn and stock? I say without hesitation that every person, whether gardener, agriculturist, mechanic, or labourer of any sort, can live from 7½ to 10 per cent. cheaper now than they could two years back, therefore the wages must come down.

"Thinker" has mentioned that our Apples go a-begging, whilst the American Apples are selling freely in our markets. It is well known that our climate will not—at least in many parts of the country—give us such hot sunny weather as our American neighbours have to produce their highly coloured Apples. If we planted all the choice American varieties very few could have them as they can be had in America. I ask, Why should we not grow Pears here to equal those from Jersey? also why not grow Grapes as cheap as those from the Channel Islands? The answer in both cases is, We have not the climate in England. We have plenty of good Apples here in a favourable season if a ready market could be obtained. In October last I was in a village in the north about 100 miles from King's Cross, where there was an exceedingly heavy crop of Apples, and there sacks, not bushels, of fruit were on the ground under the trees. I asked my friend why he did not sell these, and the answer was, It will not pay to have them gathered and packed. I thought they ought to pay a little if sent to Covent Garden Market. I asked a salesman the value and railway expenses per bushel, and found to my surprise that they would scarcely pay the cost of railway carriage and commission, the owner giving his trouble and leaving no profit. The varieties were Scarlet Nonpareil, Ribston Pippin, and Blenheim Pippin.

In the Journal, January 21st, page 42, "Utilitarian" is very hard on the farmer. He speaks as if none of the farmers have any capital, and that the market gardener can outbuy him and outwit him by bringing up his sons to work and keeping his daughters from the piano. Now I beg to differ, as I can say the market gardeners have pianos and their daughters play them equally as much as the farmers' daughters. And why should they not? May I ask "Utilitarian" what capital should a farmer have to take a farm of 200 acres, to take stock and crop his farm, and provide all implements? I say £10 per acre is the average. Now should not a man with £2000 capital have a few luxuries as well as any head gardener or market gardener?

"Utilitarian" and "Thinker" both agree that by the land-hunger of the farmer in prosperous times the small farms were thrown into large ones. Now I beg to differ even on this point, for the landlords had the small farms thrown into large ones; and where are the small farmers? They are now causing the depression in the agricultural districts, or among the farmers here by their produce from Australia, New Zealand, and America.—ONE WHO WISHES FOR FAIR PLAY.

In consequence of the unusual pressure on our columns this week we are obliged to defer the publication of several interesting articles and a series of "thoughts" on some not unimportant subjects.

— **HORTICULTURAL CLUB.**—The annual dinner of the Club was held on Thursday last, the day having been altered in consequence of the Royal Horticultural Society having arranged their annual dinner for the day on which the Club's dinner had been fixed. There was a large attendance of members, including Mr. John Lee, Chairman, the Hon. and Rev. J. T. Boscawen, Dr. Hogg, Dr. Masters, Professor Foster, Messrs. J. S. Cousens, T. P. Collings, William Bull, George Deal, Herbert Cutbush, J. F. Strange, C. P. Wheatstone, &c. Much interesting conversation took place on the condition and prospects of the Club, and the good work that it was doing, while opinions were strongly expressed that in the future it would hold a still more useful position. The next meeting was announced for Tuesday, March 9th, when it is probable that the discussion at the conversazione will be opened by Mr. Shirley Hibberd.

— "A SUBSCRIBER" writes:—"I shall be much obliged if any of your readers will inform me what is the best thing to catch MOTHS with. I have tried sugar and rum, as recommended by some entomologists, but have not found it answer."

— WE regret to have to announce the death of MR. C. FRISBY, which took place on the 2nd inst. at Branston, in the seventy-first year of his age. Mr. Frisby was over forty years gardener at Blankney, and gained considerable reputation as a practical gardener and exhibitor. He raised several florists' flowers of merit, also the Excelsior Beet, which has been found a good variety, and the Blankney Hero Melon originated in the same gardens. Several years since Mr. Frisby retired from his charge, and had since enjoyed a substantial pension from the Rt. Hon. H. Chaplin, M.P. Mr. Frisby died suddenly from inflammation.

— WE also hear that MR. HENRY BOLLER of the Woodfield Nursery, Harrow Road, died on the 3rd inst. He was well known as a cultivator of Cactaceous plants, and at one time had an extensive collection.

— A MEETING of the TURNER MEMORIAL FUND COMMITTEE was held at South Kensington yesterday, Mr. Harry J. Veitch in the chair. It was announced that a sum of £175 had been received, but it was still hoped to raise it to £200. On the proposition of Mr. G. Paul, seconded by Mr. Cannell, three trustees were appointed—namely, Messrs H. M. Pollett, H. J. Veitch, and H. Turner. It was also resolved that the funds be invested in stock guaranteed by the Home or Indian Government, and that the prizes offered will be limited to amateurs.

— ONE of the most useful of winter-flowering plants, ACACIA PLATYPTERA, is also in capital condition now, a dozen or more plants being very valuable in a conservatory. It is one of the quickest growing Acacias, and surpasses many others in flowering when quite small, while larger specimens yield a valuable supply of flowers. For decorative purposes plants in 60 and 48-size pots are most useful, and a good stock of these can be readily obtained from cuttings of the stems taken a week or two later.

— A MEETING of the GENERAL COMMITTEE of the NATIONAL CHRYSANTHEMUM SOCIETY was held on Monday last at the Old Four Swans, Bishopsgate Street, when the Floral Committee for the year was elected, together with sub-committees for various purposes, including one for the preparation of a new edition of the catalogue. The Royal Aquarium Company, Westminster, having made liberal offers of prizes, it was decided to hold three shows, one for early Chrysanthemums and Dahlias, the ordinary one in November, and a late Show in January.

— "A. L. G." writes:—"I feel flattered by the kindness shown me by a "Gardener of Great Experience." My remarks on the ANALYSIS OF SOIL were written more with the view of obtaining than giving advice. I am only a working gardener, and I think if your correspondent has any questions to ask me it would be better if it were done as suggested through the Journal." [We neither give the names of correspondents who write under initials or a *nom de plume*, nor permit them to be extracted by others. If the writers in question send us their names and addresses, and specially request us to forward them to any person, we comply with their request. If it is simply intimated to us that we are "at liberty" to disclose names, we invariably decline to furnish them to inquirers.]

— THE Council of the Royal Meteorological Society have arranged to hold at 25, Great George Street, S.W., on the evenings of March 16th and 17th next, AN EXHIBITION OF BAROMETERS, and the Secretary invites the co-operation of all interested, as it is desired to obtain as large a collection as possible of such instruments. The Committee will also be glad to show any new meteorological apparatus invented or first constructed since last March; as well as photographs and drawings possessing meteorological interest not previously exhibited.

— A FEW EARLY FLOWERS are now peeping through the ground, one of the prettiest being the Winter Aconite, *Eranthis hyemalis*, which is showing its bright yellow blossoms in abundance. Upon mounds or under the shade of trees it succeeds well, and if associated with Snowdrops it is still more beautiful. We recently saw a cheerful little spot under a Weeping Ash, where there was a liberal scattering of these winter-flowering plants, and a charming appearance they presented. Many an otherwise dull place in a garden might be enlivened by a well-considered system of arranging such early-flowering plants as those named with Daffodils, Primroses, and Scillas of the siberica and bifolia types. Planting Crocuses and other bulbs in grass is now becoming a more general practice, and it is surprising how the beauty of a garden may be diversified and prolonged by adopting such plans as these.

— A COMPARATIVELY old plant is RHODOCHITON VOLUBILE, yet

we do not see it so frequently as might be expected, though its merits entitle it to a place in every greenhouse where it is desired to have some covering for the roof rafters. It grows quickly, its slender stems extending to a great length, and bears its flowers from nearly every axil, and they remain attached to the plant for a very long time. The most conspicuous part of the flower is the calyx, which is saucer-like, over 1 inch in diameter, and of a bright rosy colour, which continues fresh while the globular fruits that assume the same tint are ripening. The corolla is of a dark purplish hue and tubular, falling off after the fruits are set. At the present time this *Rhodochiton* is very attractive trained along the roof of a cool house, and has both flowers and fruits in various stages at the same time. A main stem is taken lengthways, and then from this hang a number of secondary growths which are like wreaths of rosy flowers.

— MR. JOSEPH MALLENDER sends the following SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, Worksop, Notts, for January, 1886:—Mean temperature of month 34.4°. Maximum on the 1st, 51.3°; minimum on the 19th, 16.5°. Maximum in sun on the 31st, 90.9°; minimum on the grass on the 25th, 10.9°. Warmest day the 1st, mean temperature 48.7°. Coldest day the 19th, mean temperature 21.3°. Mean temperature of the air at 9 A.M., 33.7°. Mean temperature of the soil 1 foot deep 36.2°. Nights below 32° in shade twenty-one, on the grass twenty-seven. Sunshine, total duration in month forty-four hours, or eighteen per cent. of possible; the brightest day the 8th. We had ten sunless days. Rainfall, total amount in the month 3.24 inches. Maximum fall in twenty-four hours on the 10th 0.41 inch. Rain fell on twenty-three days. Wind, average velocity 11.7 miles per hour; exceeded 400 miles on eight days, and fell short of 100 miles on three days. Temperature below the average throughout, but the frost more remarkable for its lasting than for its severity and for the number of alternations of frost and thaw. The total rainfall (of which a large part was snow) and the number of rainy days more than in any of the previous ten years. Sunshine more than in four out of the five last years.

— AT a recent meeting of the Linnean Society, an extensive series of FOSSIL PLANTS FROM THE ISLAND OF MULL was exhibited by Mr. J. Starkie Gardner, who gave remarks concerning inferences to be drawn from the well-preserved leaves. He mentioned that this fossil Mull flora comprises but one Fern undistinguishable from living *Onoclea sensibilis* of Western America and Eastern Asia. There is an *Equisetum*. The Coniferae are abundant; a *Ginkgo* resembles existing species, along with numerous Firs and Larches, a few of these latter being similar to those of Japan. Monocotyledons are represented by one having a sword-shaped leaf. There are at least twenty species of dicotyledons. A *Platanus* obtains, differing somewhat from the recent form, and with resemblances to what is known as *Credneria* and *Protophyllum* of Cretaceous age. This Mull flora, though possessing few novelties, is interesting as supplying fresh confirmation of the view first propounded by Asa Gray—that formerly the entire northern temperate regions possessed a very uniform flora.

— ON the same occasion Dr. M. T. Masters read a paper on the HISTORY OF SOME CONIFERS, which was illustrated by living plants from Mr. Harry J. Veitch, of *Abies Fortunei*, *A. nobilis*, *A. grandis*, and *A. amabilis*; also of *Pseudolarix Kämpferi*, *Picea Omorika*, *Arthrotaxis selaginoides* with others. Dr. Masters' remarks comprised the result of observations on the mode of growth and structure of various species of Coniferae, concerning which much difference of opinion had previously existed owing to the imperfection of our knowledge. Of late years many of these species had been introduced into cultivation, and some of them had produced male flowers and cones, thus affording an opportunity for diagnosing the species and ascertaining their limitations. The study of the cultivated plants had likewise shown the natural range of variation in a species or individual plant under comparatively uniform conditions. Our knowledge of their geographical distribution has also been extended, altogether thus enabling a fresh revision to be attempted.

### SOWING WRINKLED PEAS EARLY.

"KITCHENER," in referring to the advice of Mr. Marriott to sow some each of the best Peas at the present time, repeats, in my opinion, an error in Pea culture. High-priced varieties are, I know, disliked by some employers, but with those, however, who buy and grow for their own consumption this erroneous idea is fast dying out. It should be considered that a more robust constitution has been introduced along with improved flavour. Much doubt as to the safety of early sowing is removed,

seeing that one half-pint of several new or recent introductions produces an equal crop to a quart or more of some fairly good varieties, while in point of size and quality for exhibition or profit, and I may add for a gentleman's table, comparison would go against the cheaper sorts. I have found even in the north of England in dry ground, the following may with advantage be sown in favourable weather during January and February:—Criterion, Telephone, Sutton's Giant Emerald Marrow, Duke of Albany, and Lord Bacon. Emerald Marrow I consider to be one of the best-flavoured Peas in cultivation, but not suitable for exhibition. It is a white Pea, very distinct and heavy cropper.—LATHYRUS.

### ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 9TH.

THE members of the committees and the visitors were agreeably surprised to see such a bright and extensive gathering of plants, flowers, and Apples as that presented on Tuesday last. Very seldom do the February meetings bring such effective displays, and still less could it have been expected in such severe weather; yet delicate Orchids were brought in sufficient numbers to form several beautiful groups, hardy plants were represented by several choice selections, and the display of Apples was a remarkable one for the time of year.

FRUIT COMMITTEE.—Present: Harry J. Veitch and Messrs. T. B. Haywood, R. D. Blackmore, James Smith, John Woodbridge, W. Denning, J. Willard, G. T. W. Miles, Harrison Weir, Philip Crowley, John Burnett, Wm. Paul, George Bunyard, and Dr. Robert Hogg. Mr. J. Wells, Fern Hill, Windsor Forest, sent two small bunches of Cooper's Black Grape to show its keeping qualities; they were cut on the previous night from a Vine grafted on Trentham Black. The berries were fairly plump, bearing a thick bloom and were of good flavour. The same exhibitor had two dishes of Catillac, the fruits in one having been grown on light soil and the others on clay. The former were found to be much the better, but the Committee desired to have further information respecting the stocks upon which they are worked. Good samples of Pear Bergamotte d'Esperen also came from Mr. Wells. Messrs. C. & J. W. Townsend, Fordham, Cambs., sent four samples of a seedling Apple, which was passed; as also were other seedling Apples from Messrs. Elsdon & Co., Melton; Mr. G. Collins, Stourport; and Mr. J. Corderoy, Didcot. Messrs. G. Bunyard & Co., Maidstone, showed fruits of Apples Smart's Prince Arthur, Jacob's Apple; Mr. Corderoy sent a dish of Golden Drop Apples, and Mr. R. Dean had some samples of Hambleton Deux Ans, very sound and good. Mr. Draper, Seaham Hall, Sutherland, showed a Green Kale called Draper's Seedling, which is to be tried at Chiswick.

Messrs. J. Cheal & Sons, Crawley, were awarded a silver Banksian medal for a collection of seventy-five dishes of Apples, remarkably well kept, the fruits of good size and well coloured. The principal varieties were Blenheim Pippin, Gloria Mundi, Golden Noble, Hoary Morning, Winter Queen, Worcester Pearmain, Frogmore Prolific, Loddington, Annie Elizabeth, Reinette du Canada, Hollandbury, Alfriston, New Hawthornden, Cox's Pomona, Kerry Pippin, English Codlin, Mère de Ménage, Egremont Russet, a Sussex Apple of good quality, and Warner's King. All were handsome samples of their respective varieties. Messrs. T. Rivers and Son, Sawbridgeworth, were awarded a medal of equal value for 200 dishes of Apples, comprising most of the varieties already mentioned, and specimens of the following were also notable:—Cox's Pomona, Buckingham, Barclay's Sweet, Dumelow's Seedling, Melon, Reinette du Canada, British Fillbasket, Mère de Ménage, King of Tomkin's County, Reinette Noire. Messrs. G. Bunyard & Co., Maidstone, were also awarded a silver Banksian medal for a collection of 100 dishes of Apples in admirable condition, the fruits of considerable size and well kept. Especially good were Cox's Pomona, Lord Derby, Stone's Apple, Hoary Morning, Warner's King, Peasegood's Nonesuch, Duchess's Favourite, Golden Noble, Emperor Alexander, Cox's Pomona, Lord Derby, Alfriston, King of the Pippins, Melon, Alfriston, Hoary Morning, New Hawthornden.

FLORAL COMMITTEE.—Present—G. F. Wilson, Esq., in the chair. Dr. W. H. Lowe, and Messrs. J. Douglas, W. B. Kellock, E. Hill, J. O'Brien, H. M. Pollett, John Dominy, H. Ballantine, A. Lendy, Richard Dean, W. Holmes, H. Herbst, W. Wilks, G. Duffield, H. Bennett, John Laing, James Walker, G. Paul, Thomas Baines, Harry Turner, and H. Cannell.

A cultural commendation was awarded to G. F. Wilson, Esq., Weybridge (gardener, Mr. Chamberlain) for a raceme of *Phaius tuberculatus* with a dozen of its beautiful flowers, the white sepals and petals contrasting admirably with the bronzy red mottled lip, white in the centre with a yellow ridge and pink margin. H. M. Pollett, Esq., Bickley, sent spikes of *Odontoglossum Schillerianum*, somewhat like *O. odoratum*, yellow barred with red, and a beautiful variety of *C. Trianae*. A good plant of *Cattleya Measuresiana* was also shown with four flowers, the sepals and petals greenish brown, and the lip crimson. Mr. Haywood, Woodhatch Lodge, had several pretty varieties of *Cattleya Trianae*, and a good variety of *Odontoglossum Rossi* called *ornatum*, spotted with deep crimson brown. R. J. Measures, Esq., Camberwell, showed a plant of *Cypripedium Measuresianum*, a new species from Borneo, with a green dorsal sepal and purplish petals. A cultural commendation was awarded to Mr. J. Douglas, The Gardens, Great Gearing, Ilford, for a large panicle of *Odontoglossum cirrhosum*, a distinct crimson spotted variety. A cultural commendation was awarded to Mr. Ballantine, The Dell Gardens, Egham, for a grand plant of *Cattleya Trianae Russelliana*, bearing thirteen large flowers, the sepals and petals bluish, the latter very broad, and the lip exceedingly rich crimson. Dr. Duke, Lewisham, sent a plant of *Cattleya Trianae Dukeana* and *C. Laurenciana*.

C. Scrase Dickens, Esq., Coolhurst, Horsham, was adjudged a bronze Banksian medal for a most beautiful and tastefully arranged collection of Camellia flowers, chiefly single and semi-double, crimson, pink, white, and white-striped with crimson. They were arranged upon moss with their own foliage. Mr. F. Ross, gardener to Sir G. Macleay, K.C.M.G., Pendell Court, Bletchingley, was also awarded a vote of thanks for a large plant of *Bromelia macrodora*, with large drooping spikes, the flowers greenish, and long elliptical bright red bracts. Votes of thanks were accorded to G. Nevile Wyatt, Esq., Lake House, Cheltenham, for a plant of *Cattleya Percivaliana*, with a broad expanded bright crimson lip; to Messrs. H. Cannell & Sons, Swanley,

for a beautiful collection of Primula flowers and plants representing the choicest Swanley varieties, both single and double. From the Society's garden came a group of Primula malva crisp, a variety with single white flowers and curled foliage. Mr. J. James, Woodside, Farnham, sent two Cineraria, very fine varieties, richly coloured; and Mr. Woolford, gardener to H. Palmer, Esq., East Thorpe, Reading, had some fine crimson Primula named Mrs. Palmer.

Mr. T. S. Ware, Hale Farm, Tottenham, was adjudged a silver Banksian medal for an interesting group of hardy plants, comprising Cyclamens, Irises, Galanthus, and Crocuses. Cyclamens Comm album, roseum Atkinsi, purpureum and album were well represented by specimens in pans about 9 inches in diameter. Iris reticulata and its variety Kelagel were very attractive. Crocus Imperati and the variety longiflorus were good, the latter deeper rosy crimson in colour. The charming white Narcissus monophyllus was excellent. Messrs. Burr & Son, Covent Garden, showed a small collection of Hellebors, varieties of orientalis, abchasicus and guttatus and colchicus, dark and light, the latter with dark spots. A few Cyclamens of the C.ibericum, C. Comm, and C. Atkinsi were also staged with two grand pans of Galanthus Elwesii, the flowers very large and beautiful. Messrs. Collins Brothers & Gabriel, 39, Waterloo Road, London, S.E., had a beautiful collection of Narcissus, comprising twenty-four varieties of the most diverse form and size. They had been grown in pots in a frame, and were as fresh as could be wished. Owing to their earliness they attracted much attention. Some of the best varieties were Princeps, creamy sepals, yellow tube; moschatus, white; bicolor Horsfieldi, white sepals, yellow tube; obvallaris, golden yellow, beautiful form; incomparabilis plenius, double orange and white; triandrus, a charming diminutive creamy yellow flower; Corbularia citrina, Graefii, and alba, three pretty varieties of Hoop Petticoat Narcissus; pallidus pæcox, one of the earliest of all the Daffodils; maximus, very large and bright golden yellow. A few Lachenalias and Galanthus Elwesii served to brighten the collection, for which a silver Banksian medal was awarded.

Mr. C. Turner, Slough, was awarded a bronze Banksian medal for a group of strongly grown white Cyclamens, the flowers of which were very large and of great substance. A similar award was adjudged to Messrs. Heath & Son, Cheltenham, for a group of Orlontoglossum Roezli and the variety alba, exceedingly well-grown plants, bearing several spikes each. Some plants of a species of Ficus were also sent by Messrs. Heath, the leaves elliptical and dark green. A silver Banksian medal was awarded to the St. George's Nursery Company for a large and handsome group of Cyclamens, exceedingly well-grown plants, most varied in colour, rich, delicate, and pure white.

#### PLANTS CERTIFICATED.

*Cattleya Trianae Schroderiana* (Ballantine).—A magnificent Orchid, one of the grandest Cattleyas yet obtained. Sepals and petals faintly tinged with pink, the petals  $3\frac{1}{2}$  inches in diameter, the lip  $2\frac{1}{2}$  across, brilliant crimson with a yellow throat. The plant shown had twenty-one flowers.

*Cattleya Trianae Ernesti* (R. J. Measures, Esq.).—A lovely variety, the sepals narrow, bluish-tinted; the petals broader, similar in colour, but tipped with crimson; the lip of a most intensely rich crimson at the upper half, white or blush towards the base.

*Iris reticulata cyanea* (Ware).—This chiefly differs in the flowers being smaller than *Iris reticulata*, with more blue colouring.

*Primula floribunda* (Ware).—A charming little Primula. The flowers bright yellow, small, in umbels about 6 inches high. Very pretty and free-flowering.

*Galanthus Elwesii* (Barr & Son, and T. S. Ware).—A beautiful Snowdrop, one of the best in cultivation. The inner divisions of the perianth are white, green at the base, and green streaks on the inner surface; the outer divisions are white, large, oval, and spreading sometimes as much as 1 inch in diameter.

*Arum pulestinum* (Heath & Son).—A curious species, with leaves somewhat like the common Arum; the spathe about 7 inches long, dark maroon, and the spadix about the same length, quite black. This is the plant which has gained the title of the "Crimson Calla" in the United States.

#### THE LATE MR. JOHN ROBSON.

I REGRET to see in the Journal an account of the death of my friend Mr. John Robson, and can testify to the accuracy of the well-merited eulogium therein passed upon him. I have had the pleasure of his friendship for the past twenty years, and in my opinion it would be difficult to find a more genial or kindhearted man, and one who was more beloved and respected by all acquainted with him. It was in connection with the Maidstone Gardeners' Society where I and many others best knew his worth. It was mainly through his administrative ability and wise counsel, as well as co-operating with such well-known men as Mr. Davis at the cemetery, who is not inaptly termed the father of the Society; Mr. Bradley, late of Preston Hall; the late Mr. Thomas Frost, nurseryman; Mr. Harrison, seedsman, and others that the Society has been raised to one of the best and one of the most useful in the country. It was a pleasure to be present at a meeting when he was chairman and hear him unfold his practice and ideas in such a lucid manner of whatever subject was brought before him for discussion. He was particularly happy when it was a young gardener who sought his advice, and if he could not then devote the time to fully go into the matter and send him home happy, that man might be confident of a communication by letter giving him the best advice in his power. He was a well learned man in all matters connected with gardening, especially in the designing for ground work, also his sound and true judgment of the effect of different landscapes, the effect and influence of different soils on the growth of timber trees, the geological formation of the earth in different parts of the country and its influence on vegetation, were his favourite topics of conversation; and he has more than once remarked to me that he hoped to live long enough to see young gardeners take more interest in ground work, a knowledge of which he found young men as a rule lamentably deficient. His pre-

diction was that such knowledge would bring about more stability and a better understanding between employer and employee. He was a man of noble mind and thought, and always upheld his profession in a true and manly way, and one whose example many would do well to imitate.—T. RECORD.

THE announcement of the death of this gentleman in last week's Journal would be read with great regret by many friends besides myself. It has been my privilege to know him as a most kind friend, and part of the time—1872 to 1875—as a master. In the ten years following that time in pursuit of knowledge and experience I moved to various parts of the country, and had several masters, but never afterwards did I meet with his equal. He was kind and encouraging to young men under him, and watchful of their interests afterwards. His store of knowledge was very great, and was always at the service of his humbler brethren, and especially his young men; indeed nothing seemed to give him so much pleasure as helping others by advice and information.

Most of the readers of our Journal will remember his contributions to its pages up to the time he was laid aside by illness, and was obliged to resign his situation in consequence. His articles were always so full of sound instruction and common sense, because written from practice and personal experience. At that time the gardens at Linton were especially noted for their fine collection of hardy plants, flowering trees, and shrubs, &c., in which he took great interest, and also in the splendid collection of Conifers, which are still to be seen. He also took especial interest in the formation and management of the Maidstone Gardeners' Mutual Improvement Association, and acted as Chairman of its meetings for a long period. Many are the useful and practical lessons he taught the members, and in this sense his place at the meetings has never since been filled. The members showed their appreciation of his services by presenting him with the handsome gold watch and chain alluded to in your last issue. Later on he also very largely assisted in the management of the Broughton and Linton Society, which was formed on much the same plan as the parent and larger one at Maidstone.

A man of such experience and ability was certain to make many friends, and what is more, he never lost them afterwards, but was very much esteemed by all classes in the neighbourhood, which was conclusively shown by the splendid testimonial presented to him on resigning his arduous charge at Linton, also referred to in your last number. His was a useful and well-spent life, in which every opportunity was seized of doing good to others—a kind husband, a good father, and a firm and faithful friend, he set an example for us all to follow.—W. H. DIVERS, *Ketton Hall*.

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual meeting of this excellent and flourishing Institution, which has been established twenty years, was held on Monday evening last in the Society's room at the Caledonian Hotel, Strand, London, Mr. Richard Dean, one of the honorary members, presiding. The Chairman, in opening the proceedings, adverted in appropriate terms to the great usefulness of the Society, testified to the admirable manner in which it is conducted, and expressed his strong conviction that if the advantages offered were fully appreciated by gardeners that the accession of members, great as it has been during the past few years, would be still greater. In that expression of opinion we join. It should be stated that no pecuniary interest whatsoever is derived by the directorate, the only subsidy granted being the balance that there may happen to be in favour of the Society in the management fund, and this is granted to the Secretary as a small recognition of his valuable services, the amount this year being £5 7s. 9d. When it is considered that every one of the 169 members is provided with a separate balance sheet annually, showing the exact amount that is banked to his credit, apart from the ordinary routine of book-keeping under the three separate heads—Benefit Fund, Benevolent Fund, and Sick Fund—it will be conceded that it is quite incommensurate with the services rendered as estimated on a strict commercial basis. Mr. McElroy, in fact, works not for gain, his chief reward, as he stated in his modest response to the enthusiastic vote of thanks accorded, being the luxury of being able to grant relief in sickness, and to minister to the pressing needs of the widows and fatherless in the time of sorrow that they may be called to endure. According to the rules of the Society he is entitled to a more adequate recompense, but this is waived in the interests of the members.

Although the constitution of the Society has been previously described in these columns, its main features may fittingly be recapitulated as reminders to old and as information worthy of the attention of new readers. This cannot be more concisely given than in a few citations from the rules. First we observe that—

"In this Society there are no entrance fees or fines for non-payment of subscription. Rule 14 especially should be noticed.

"No fund is provided for funeral money, as every member provides for this event by investing his own capital at interest. See Rule 16.

"Attention is particularly called to the Benevolent Fund. See Rule 18. This rule should be carefully read in order to appreciate the many benefits to be derived."

From the table of contributions and benefits we find that for insuring 10s. 6d. per week for twenty-six weeks members pay to the Sick and Deposit Fund 2s. annually, to the Benevolent Fund 2s. annually, and to the Management Fund 2s. 6d. annually. For insuring 16s. weekly the payments are 3s., 2s., and 2s. 6d. respectively.

"After twenty-six weeks full allowance, half the amount is allowed for twenty-six weeks more, he is then transferred to the Benevolent Fund, to receive such sum as the Committee deem fit. During the time he is on the Benevolent Fund no money is taken from his deposit. See Rule 14. No sum is provided for at death, as the member's deposit (see Rule 16), with the interest accumulating, will more than counterbalance any funeral money. Should any member die in straitened circumstances, the Committee are empowered to assist the widow and children (if any). See Rule 18. After attaining seventy years of age the member ceases to pay into the Sick Fund at all, and he is provided for from the Benevolent Fund in case of sickness or distress, irrespective of any sums he may have invested. See Rules 14 and 18."

Relative to the constitution of the Society, Rule 3 states:—

"That this Society shall consist of an unlimited number of members who follow the calling of gardeners, whether in nursery gardens, private gardens, market gardens, or seed warehouses; none other but gardeners to be eligible to become deposit members and recipient of relief from the Sick and Benevolent Fund."

The admission of members is made clear in Rule 13:—

"That no person shall be admitted a member of this Society under the age of eighteen or above the age of forty-five years; and has worked not less than three years in a garden. Any gardener wishing to become a member of this Society shall forward to the Secretary his name, age, and residence, and whether married or single; also accompanying it, if required, procured at his own cost, a copy of the register of his birth (or baptism if before the register was first used), or some other evidence as to his age which shall be satisfactory to the Committee, and a certificate from a properly qualified medical practitioner as to the state of his health, this certificate to be forwarded in a sealed cover if the surgeon deems it advisable. If residing at a distance from London the medical certificate to be countersigned by a clergyman of the Established Church, or a magistrate, or a well-known gardener or nurseryman, as would be most convenient, that there may be no doubt as to the right person being described."

Rule 14 points out:—

"Whilst a member is in receipt of sick-pay, no larger amount than two days' sick-pay monthly may be received from him, but at all other times he may pay in any sum he can afford to lay by, and the same will be carried to his account as stated in Rule 16. As all members pay the same contributions, and no entrance fees are required, a member's deposit, while he is in receipt of sick-pay, shall be liable to the following deduction, for the benefit of the Benevolent Fund, viz.:—For every 1s. he receives, a deduction of one halfpenny, if he was under twenty-five years of age when admitted; 1d. if between twenty-five and thirty-five; 1½d. if between thirty-five and forty-five."

"The payments in case of sickness to be made in full from the Sick Fund for twenty-six successive weeks, half the amount for the next twenty-six weeks, providing the member's deposit can supply the above deductions; if not, and his sickness continues, he shall be considered as permanently disabled, and transferred to the Benevolent Fund, and he will not again have a claim for sick-pay from the Sick Fund until he has been free from illness for six months."

"Any member allowing his subscription to fall twelve months in arrear will be considered to have left the Society, and his account will be closed in the books; he will not lose his deposit—it will not, however, be paid to him, but be retained by the Society until he attains the age of sixty years; or should he die before that age be paid to the person nominated by him; the amount paid will be the sum total that stood in his name at the time of his allowing his subscriptions to fall in arrear; all interest on such amounts after this period will be handed to the Benevolent Fund."

"Should the amount of sickness during any one year be more than the subscriptions of members will defray, the deficiency to be deducted from each member's deposit in equal proportions."

"No payments will be received from any member on account of the Sick Fund after he reaches the age of seventy years, and he ceases at that age to have any claim on it in case of illness, being provided for by the Benevolent Fund."

According to Rule 15:—

"A member is considered sick and entitled to sick-pay when he is wholly unable through illness to do his usual work. No member to be entitled to sick-pay until he has contributed twelve calendar months. . . . If the sickness of a member is not such as wholly to disable him from work, or if he becomes convalescent and able to earn a little, though still unable to follow his customary employment, the Committee may, if they think fit, on a recommendation in writing from a properly qualified medical practitioner, allow him to do such work as he can, and make a proportionate deduction from his sick-pay."

We now come to a distinct and very important provision—namely, that the surplus of every member's contributions, after the yearly demands on the Society for sickness, &c., are met, is invested for him, and the sum, with all interest accruing, is his own property absolutely, payable to him if he attains the age of seventy years, or to his nominee (whom he appoints when joining) whenever his death may occur. That is the substance of Rule 16. As examples of its practical working we inspected the account of one of the oldest members, which amounts to nearly £50, the yearly interest on which is a substantial approach to the amount of his contribution. That is the member's own money, and will go on increasing as long as he contributes. The total share of liability of each 16s. a week member is this year 2s. 5d.; of 10s. a week members, 1s. 10½d.; their payments beyond that going to their deposit accounts. An example of a member's deposit being actually paid during the year to his nominee is afforded in the case of the late Mr. Edward Rowe, who died at the age of forty-six, and whose widow received £34 12s. 3½d. apart from the sum of £8 16s. paid during the member's illness."

Rule 18 governs the Benevolent Fund, and is worthy of being quoted in its entirety, as follows:—

"This fund shall consist of all moneys handed over by the United Horti-

cultural Society in conformity with their rules; also the annual contributions of members, as stated in Rule 14, and the donations of patrons and contributions of honorary members specially given for this purpose. Honorary members' subscriptions to be one guinea per annum, or ten guineas paid in one sum."

"The sum so raised year by year shall be applied towards rendering assistance to members who have passed their seventieth birthday, to such an amount as the state of the funds will admit and the Committee deem advisable, consideration being given to those who have used the best exertions to lay by a provision in old age by keeping a good deposit balance."

"Every member also who has the misfortune to be ill for a longer period than fifty-two weeks will be eligible to receive relief from this fund, the Committee to determine the amount to be allowed. Subscribers of 21s. and upwards per annum, being professional gardeners, shall also be eligible as recipients from this fund, should they be at any time placed in such a position as to require assistance."

"Should any member or subscriber, being a gardener, die in straitened circumstances, leaving a widow or widow and children, the Committee shall, on the case being brought before them, investigate it, and afford such temporary relief as they may deem requisite and necessary."

"Should any member receiving sick-pay from the Sick Fund meet with any accident, such as a broken limb or dislocation, the Committee shall have power to pay such sum towards his surgeon's account as they may deem expedient from this fund."

"The Committee of Management to have power to relieve members of this Society from this fund as they may deem advisable."

That this fund is freely applied when necessary is shown by the case of Mrs. Rowe, who died within three months of her husband, leaving four children quite unprovided for (one seriously afflicted), the Committee, with a full knowledge of the circumstances of the case, granted £20 from the fund in question to meet the urgent wants of the orphans."

It will be seen that the Society is established on a broad basis for the benefit of its members; and that it is sound is testified by the results. As intimated, whatever surplus there may be in the Management Fund is granted to the Secretary. It is the Benefit and Benevolent Funds that are the test of stability; and last year the amount of the former was £1986 2s. 7½d.; this year it is £2241 6s. 4½d., while the Benevolent Fund last year was £972 15s. 10½d., whereas this year it is £1038 2s. 11d. A sum of £300 has been invested in 3 per cent. consols during the year, making a total of £3300. And all the business of this healthy society is transacted at a cost (including the gratuity to the Secretary) of £23 16s. 1½d., this being the total of the Management Fund. If by any means this fund could be increased, there is little doubt that a great accession of members might be secured, and the institution become in a broad sense a National Gardeners' Benefit Society. Possibly, if honorary members had the option of contributing to this fund their numbers might be increased; at present they are disproportionately small—namely, William Marshall, Samuel Morley, James Brand, H. J. Atkinson, and A. H. Lancaster, Esqs.; Messrs. Clay & Levesley, R. Dean, W. Paul, G. Paul, J. Veitch & Sons, B. S. Williams, and J. Wright. A donation of £10 10s. constitutes a life membership, honorary members' annual subscriptions being £1 1s."

The election of the Committee—Messrs. Cole, Scott, Coates, Wood, Morland, and Campbell—with sundry votes of thanks, brought the meeting, which was largely attended, to a close."

## STRAWBERRY PLANTS IN WINTER.

I WAS pleased to see the contribution from Mr. T. Challis on this subject (page 61). I am, however, sorry he did not state as near as possible the time he stacked his plants in autumn and the time they are stood upon the surface in spring. This is a matter of some importance in carrying out this principle of preserving the plants in winter. If stacked too early in autumn they become unduly dried even before the approach of severe weather, but this in a measure I know could be guarded against. Again, in early spring, even before the winter has well passed, I have seen the plants almost shrivelled by the influence of drying winds. I have tried this system, and the last time I stacked the plants I took them all down early in February and found fully three parts of them dust dry, this being the result of a week's drying winds. For the plants to be in this condition during the resting period is not natural. Are plants placed in the soil outside in this condition during the winter? They certainly have more moisture at the roots during that period than probably at any other. I have just examined the condition of the soil of the plants plunged upright in pots and that of those planted out, and there appears very little difference, if any."

Lately we have had some peculiar weather here—frost, snow, rain, and frost again day after day at intervals of a few hours. Such weather, frost and thaw in rapid succession, is certainly bad for any plant whether in a pot or planted out; but during the seven years I have practised the system advocated I have never found the plants injured in the manner described by Mr. Challis. I reside in a very damp wet locality, and have up to the present time found the plan of plunging the pots upright to answer perfectly, and therefore I have no reason to change it for one liable to subject the plants to a system of drying which I consider unnatural to the Strawberry.—A NORTHERNER.

## MILDEW ON ROSES.

HAVING read much in the Journal about mildew on Roses for the past two seasons is the only excuse I have for giving you my experience on this matter. Eleven years ago I took my first charge of a garden, which was in the county of Durham. I went there on the 4th of June, and found about fifty pot Roses so badly infested with mildew that I

thought it almost impossible for them to do any good that season. I placed them all together into a light airy house, shortened the shoots as far as I thought necessary, syringed them twice a day forcibly with cold water, and watched them carefully that they had sufficient water at the roots. Signs were soon noticed of buds starting out of one or two-year-old wood, and also from the base of that season's wood. At the end of August I had them with clean heads of bloom. The next year we increased our stock and started syringing early, and kept on all the season and during the nine years I had charge we had no more mildew.

I left two years ago this spring to take charge here, and I found one house of Roses in pots and planted out, with about 800 in beds and borders (in the gardens), and that autumn we started a second house of Roses in pots and planted out. Having a good force of water laid on from the lawn in all the houses I got two lengths of Merryweather's red roller pipe with a rose at one end, and made it to fit our taps in the houses, and gave our Roses the full force of water over and under them just as it comes from the pipes twice a day after February is out, and I have had no mildew the last two seasons. Our inside Roses will be started this week, and will be syringed once a day for this month, after which they are syringed twice a day till September. Our Roses inside are grown for cutting, and we cut every morning before the syringing, so that the water never spoils our blooms, but keeps them free from green fly and mildew. Our houses are light and airy, and the Roses are fed with manure.

The outside Roses are treated similarly once a week after May is out—that is, in fine weather. They are cut-dressed with manure, and they have had no mildew on them the last two seasons. I hope, with the same treatment, to keep the Roses as free from mildew in the future as I have done in the past.—E. H. BRADLEY.

#### BIRMINGHAM GARDENERS' IMPROVEMENT SOCIETY.

I HAVE been requested by Mr. Latham and other friends to ask the favour of publicity in the Journal for a notice of the proposed Society as per enclosed. It was an admirable representative meeting, and the Mayor gave much excellent advice and fully entered into the spirit of the meeting: 170 gardeners and others have already become members, and a much larger number will join. The proposal to establish such a Society was made at the annual dinner of the British Chrysanthemum Society by Mr. J. Hughes, the Secretary, and was warmly taken up. Appended is the report.—W. D.

Last evening, in the small Lecture Theatre of the Birmingham Midland Institute, a well-attended meeting of gardeners resident in Birmingham and the neighbourhood was held for the purpose of forming a gardeners' mutual improvement society. The Mayor presided, and there were also present on the platform Messrs. W. B. Latham, R. H. Vertegans, J. Pope, W. Spinks, W. Dean, J. Horton, A. Grice, J. Cole, and J. Hughes. The Mayor, in opening the meeting, said that he was very glad to find, both from the large attendance and from the support which Mr. Hughes had obtained, that the suggestion to form a mutual improvement society for the gardeners of Birmingham and its neighbourhood had met with very general acceptance from those who were most nearly interested. They followed a pursuit of very great interest. It was of such interest that many persons who were not in their way of business would be glad, if they could afford the time, to give up their own avocations and devote themselves chiefly to the cultivation of flowers and plants; and he thought it might be quite as interesting to those who depended upon it for a livelihood as to the amateur. It was a pursuit, moreover, which was interesting and beneficial just in proportion as it was approached with intelligence and not with stupidity. If a gardener went to his work with a cultivated intelligence, ready to accept new ideas, he would not only make an infinitely better servant to his master, and a much better and more respectable member of society, but have twice as much pleasure in his work as one who did it just as it came to his hand. (Applause.) There were among the gardeners of Birmingham men as well advanced in their craft as would be found anywhere, and therefore one approached the formation of such a society with confidence that men would be found who could work it. It was proposed, he understood, that they should have some room, as conveniently situated as possible, properly furnished, and, he hoped, to be in due time provided with a good library. (Hear, hear.) By the opportunities of conference which would thus be afforded, not only would those who were ignorant acquire knowledge, but those who had the very widest experience might be able to learn from some others who perhaps had had special means of information in particular branches. There were certain extensions which the society might make hereafter. The suggestion had been made that it should undertake the flower shows which had hitherto been held under separate management in the Town Hall. (Applause.) Union was strength, and the spring show might be managed with the Chrysanthemum show at very much less cost of labour and trouble. He was told that in other large towns, such as Liverpool and Manchester, there were already flourishing associations of gardeners, and he did not see why Birmingham should be any longer behind. (Applause.) On the motion of Mr. Dean, seconded by Mr. Latham, it was resolved that a Gardeners' Mutual Improvement Society be formed, with a managing committee of twelve members, to be elected annually. The resolution gave rise to some discussion, in which the study of botany was urged upon those present by several speakers. The subscription was fixed at 2s. 6d. per annum, and some donations to the library were announced. The meeting closed with a vote of thanks to the Mayor.

#### PLANTS CERTIFICATED IN 1885.

MR. W. BULL'S, CHELSEA.

FOR many years ornamental-foliage plants and Orchids have constituted two important specialities at Mr. Bull's King's Road Nursery, and we have a good illustration of this in the relative numbers certificated

at the leading exhibitions during the past year. Of a total of twenty so honoured, eight were "foliage plants," as they are termed, the same number were Orchids, and the remaining four were an *Aristolochia*, an *Eucharis*, a *Hæmanthus*, and an *Azalea*, to be noticed presently. Although the chief features are thus shown, they are by no means the only ones, for extensive collections are grown of *Pelargoniums*, *Azaleas*, *Rhododendrons*, *Chrysanthemums*, and miscellaneous flowering plants. Of the *Rhododendrons* in particular there are some thousands of seedlings, hybrids of the *R. javanicum* and *R. Brookeanum* types, that may be confidently expected to produce some beautiful novelties.

Orchids occupy much the greatest space, and it will be therefore fitting to refer to those certificated first. Taking them in alphabetical order we have *Angræcum* or *Aeranthus Leonis*, which was shown at South Kensington on the same day by five orchidists. This Orchid will be principally valued for its floriferous habit, and the flowers being white will also render it a favourite with many. As a free-growing plant that anyone can cultivate in moderate heat it is undoubtedly worthy of attention, though less imposing than the remarkable *A. sesquipedale*, to which some have compared it. A trio of *Dendrobiums* come next in order, the charming and now well known *D. Ainsworthi* having been certificated by the Royal Botanic Society, though it was first honoured by the Royal Horticultural Society in 1874. It is strange it has never been shown at Regent's Park before, but stranger still if it has been exhibited and was never duly recognised until last year. *D. crassinode album*, a white-flowered variety of a favourite and easily grown Orchid, and a highly coloured variety of *D. nobile* entitled *insigne*, are both good additions to the list. *Lycaste Skinneri alba*, the valuable White *Lycaste*, a handsome Orchid with pure wax-like flowers of great substance. An exceptionally fine white variety has now been flowering in Mr. Bull's nursery for some time, and the flower is still in good condition, the sepals and petals broad and beautifully proportioned. All the varieties of *Lycaste Skinneri* are useful owing to the durability of their flowers, but the white one is specially so because it contrasts well with the more numerous dark forms, and it is scarcely rivalled amongst white Orchids for massive purity. *Masdevallia Wagneriana* is one of the dwarf small-flowered species, with rather pretty yellowish blooms, and might be associated with *M. Shuttleworthi*. A pair of *Odontoglossums*, *O. Insleayi splendens*, and *O. Rossi concinnum*, the former a grand variety with yellow flowers richly spotted with red, and the latter a pretty little variety with symmetrical flowers, the sepals and petals broad and rounded.

We may now briefly glance at the Orchids in flower at the present time, and although February is not quite the month for a brilliant floral display, several houses contain a good show of blooms, far better than could be expected. It also proves how useful Orchids are at a time when flowers are most welcome. The *Cattleyas* are in grand health and showing sheaths by hundreds, the flowers of some varieties being expanded, and their numbers will soon be increased. A group of *C. Trianae* varieties is prominent in one house, differing greatly in colour from the pure white *alba* through delicate rose and blush tinted forms like *bella*, *delicata*, *ampliatas*, *rosea picta*, *Vesta* and *tyrianthina* to the deeper coloured *illustris* and *Imperator*. *C. Percivaliana* is also represented by some richly coloured forms, and it varies considerably in merit. A deeply tinted variety of *L. anceps* is notable in one of the houses, as also is *L. Lindleyana* with pale sepals and petals and a bluish lip. The free and long-lasting *L. alba* and its variety *L. Mariana*, with the rich and handsome *L. autumnalis atropurpurea*, are thoroughly useful Orchids, and it is astonishing how well they flower when receiving fairly careful attention.

Several *Odontoglossums* impart their attraction to groups in the houses, such as *O. mirandum*, a distinct form, with long narrow sepals and petals, brownish red in the centre, and clearly margined with yellow; *O. mulus*, barred with dark brown on a yellow ground; *O. hebraicum*, creamy white, dotted with brownish red; and *O. crispum*, superb in size and form. Of *O. Rossi* there is a group including some distinct and beautiful varieties. One form of *O. Rossi majus* is especially handsome, and well merits the three crosses on the label, which serve to distinguish it when not in flower. The ground colour is clear white, and upon this are a number of very dark reddish crimson spots that show up admirably, and with the pale yellow crest serve to render it one of the best we have seen. The others differ greatly in the size of the flower and the richness of the markings, but all are good, and the smaller flowers are generally the finest in colour. The plants of *O. vexillarium* are in excellent health, and will contribute to the floral effect later on; they are now as fresh and vigorous as anyone could wish to see. *O. Phalænopsis* is similarly satisfactory, both Orchids which are found difficult to grow by some persons, but which at Chelsea luxuriate in the London smoke. One of the chief points with these, as with other Orchids, is, in Mr. Bull's opinion, keeping the plants thoroughly clean; a little labour expended in cleansing them at stated intervals is well repaid, and is a practical illustration of the maxim that "Prevention is better than cure."

Many more Orchids might be enumerated, we can only note the following as flowering now. A new and fragrant *Dendrochilum*, which is to be referred to a botanical authority for its name; *Angræcum citratum*, very free, small plants in thumb pots bearing four spikes of creamy-white flowers; *Saccolabium giganteum*, with a fine raceme, very sweet; varieties of *Lycaste Skinneri*, delicately and richly coloured; the useful *Ada aurantiaca*; several small-flowered but interesting *Masdevallias* like *M. polysticta*; *M. E-tradæ*, and *M. simula*, with the peculiar *Pleurothallis ornatissima*, which has small white filaments pendulous from the flowers, and giving them a strange appearance. *Cypripedium Lawrenceanum*, *C. Swartzianum*, *C. Argus excellens*, a bold, handsome variety; *C.*

hybridum, *C. Danthieri*, and *C. Warneri* are all in flower. In one house in the old nursery is a group of *Cœlogynes*, principally the *Chatsworth* variety, which has six, seven, and eight flowers in a spike, and the buds in opening have a brownish appearance outside, which readily distinguishes them from other forms. Amongst some *Oncidiums* in flower was *O. Phalænopsis*, and a note on this must conclude the remarks on the Orchid collection. It is a charming species far too seldom seen; the flowers are white with bright purplish crimson blotches on the sepals and petals and at the lower portion of the lip.

The fine-foliage plants certificated were *Alocasia Sanderiana*, a bold

green, with bands of white from base to apex, a very distinct and striking plant.

The general collection of foliage plants is remarkably rich in Cycads, some extremely handsome specimens of all sizes being grown in the large conservatory. Ferns also are numerous; Palms, *Dracænas*, *Crotons*, *Bromeliads*, and *Aroids* of various kinds, such as *Dieffenbachias*, *Alocasias*, and *Anthuriums* occupy several houses.

The flowering plants comprised *Eucharis Mastersi*, a species with smaller flowers than *E. grandiflora*, but pure white and without the corona that some consider a disfigurement in the latter. *Hæmanthus*

FIG. 19.—ARISEMA FIMBRIATUM.

handsome plant, of an intensely dark green with strongly marked silvery veins. *Bentinckia condapanna*, a pinnate-leaved Palm, of elegant habit, the ribs yellow. *Caladium Comtesse de Maille*, one of the semi-transparent varieties veined with red and margined with green. *Euterpe plumosa* is a graceful, pinnate-leaved Palm, having as the name implies a feathery appearance, and *Oreodoxa plumosa*, another Palm, is similarly elegant in habit. *Sarracenia Atkinsoniana*, one of the *S. flava maxima* type, but really a hybrid between that and *S. purpurea*. The pitchers are tall and green with a broad lid and red veins. *Vriesia janeirensis variegata* is a *Bromeliad* with leaves 18 inches long and 3 inches broad, bright

*Kalbreyeri maximus*, a variety with large globular heads of brilliant scarlet flowers. *Aristolochia elegans*, a curious species of Birthwort with saucer-like flowers 3 inches in diameter, white marbled with crimson purple; and *Azalea Illuminator*, one of the *amoena* type with rosy purple flowers of good size. An *Azalea* now flowering in the nursery is very attractive, and though not a novelty it is by no means common; this is *A. balsamiflora*, which has reddish salmon-coloured double flowers of excellent form, very neat and well adapted for cutting. Some fancy winter-flowering *Carnations* are also bright and pleasing, three new varieties being especially notable—namely, *J. Veret*, crimson streaked on a light

ground; Claire Varichon, shaded with pale pink; and Jean Naturelle, crimson shaded, large and handsome. Flowering Aroids, like *Anthurium Andreanum* and *A. Schertzerianum*, are much grown, and one group of another genus, *Arisæma*, not quite so well known, includes a species, *A. fimbriatum*, of very distinct characters. Like others of the same genus, it is tuberous, bearing trifoliate leaves and spathes striped longitudinally with white on a purplish ground. The spadix is long and pendulous, and densely clothed with fine dark filaments. These characters are shown in the woodcut (fig. 19) lent by Mr. Bull, which also conveys a good idea of the general appearance of other allied species.

### NOTES ON GRAPES.

#### MUSCAT OF ALEXANDRIA AND BOWOOD MUSCAT.

FOR ten years I have been a careful reader of the Journal, and having profited much by its teachings I venture to give my experience with the above Vines. Five years ago I took charge here, and found in a mixed Muscat house one Vine of Bowood Muscat and three of Muscat of Alexandria, two grafted on different stocks, and one on its own roots, Mrs. Pince, Madresfield Court, and Muscat Hamburg being also represented. The last named was discarded owing to its colour. I have each year noted that Bowood Muscat was ten or twelve days earlier than Muscat of Alexandria, and produced bunches more freely, set its berries better, and is more robust in growth. I, however, fail to see any difference in the shape of the berries, though Bowood swells its fruit rather larger than its parent. I will give my experience of last year. In May, just as our Muscats came into flower, our boiler, a large tubular one, broke down, and for twenty-five days we had no fire—a very anxious time for me, as the thermometer stood at 44° several times; but one morning, finding it had fallen to 41°, I got desperate, in fact gave up gardening and turned engineer and general labourer until the work was completed, and informed my employer that our crop would be lost; but although Muscat of Alexandria and Mrs. Pince failed to set a full crop, I had a lot of thinning to do with Madresfield Court and Bowood Muscat. The second week in September the Bowood was ripe, and on the rod bearing sixteen bunches, averaging 2½ lbs. each, you could not point to one deformed bunch. Madresfield Court coloured well, without any sign of cracking, while Muscat of Alexandria and Mrs. Pince failed to stone the berries they had set. Any Grape-grower could not fail to see a difference in the varieties as they grow here, but put them—a bunch of each—on a stand, and show them as two sorts, and I will leave it for better judges to point out the difference in the berries. Although I have seen Muscat of Alexandria and Bowood Muscat shown in a collection of four varieties, and carry off chief honours.

As I am going to try sulphate of ammonia on our Vine borders, I shall be glad to hear if any of your correspondents have used it, and if so, in what proportion and with what result.—G. G.

### ROYAL HORTICULTURAL SOCIETY.

#### ANNUAL MEETING.—FEBRUARY 9TH.

THE annual general meeting of this Society was held on Tuesday last in the crush room of the Royal Albert Hall, there being fairly good attendance of Fellows and the following members of the Council were also present:—Sir Trevor Lawrence, Bart., M.P., presiding; the Hon. and Rev. J. T. Boscawen, W. Lee, Esq., G. F. Wilson, Esq., F.R.S., Colonel Trevor Clarke, Dr. Robert Hogg, W. T. Threlton Dyer, C.M.G., Professor Michael Foster, E. G. Loder, Esq., Major F. Mason (Secretary), and William Haughton, Esq. (Treasurer).

Sir Trevor Lawrence took the chair at 3 P.M., and the proceedings commenced by the Secretary reading the notice convening the meeting and the minutes of the last general meeting. The names of fifteen proposed Fellows were then read and their election ratified in the usual way. Dr. M. T. Masters and Mr. James Douglas were then appointed scrutineers of the ballot for officers and new members of the Council, the result being as was subsequently announced that the following were elected as officers for 1886:—President, Sir Trevor Lawrence, Bart., M.P.; Treasurer, William Haughton; Secretary, William Lee (Downside); Auditors, John Lee, James F. West, William Richards. To fill the vacancies on the Council caused by the retirement of G. T. Clark, F. Du Cane Godman, F.R.S., and Sir P. Cunliffe Owen, K.C.M.G., C.B., C.I.E., the following gentlemen were elected:—Sydney Courtauld, A. B. Mitford, C.B., and Baron Schröder.

This concluded the principal formal introductory business, and Sir Trevor Lawrence then rose to make a few comments upon the Annual Report and the position of the Society. He stated that the Council regretted they had only recently been able to circulate the terms of agreement between themselves and the Committee of the Indian and Colonial Exhibition for the present year. There was a serious curtailment of the Fellows' privileges in the tickets of admission being rendered non-transferable; this was the only difference, but it was an important one, and the delay had been caused by the efforts made to procure the same terms as in previous years. The Exhibition Committee had, however, been unable to agree to that course, and he (Sir Trevor Lawrence) believed that the matter had been referred to the Financial Committee, and definitely refused on the ground of the heavy expenses incurred in the past years. The maintenance of the Garden had been a great expense, and in 1885 the autumn weather was so unfavourable the number of visitors had been reduced considerably. For these reasons the Committee of the Exhibition for 1886 felt it was absolutely necessary to conduct their arrangements as economically as possible, and in consequence the Fellows of the Royal Horticultural Society had to submit to this restriction.

The President then referred to the fact that two meetings were called last year to consider the desirability of holding an international horticultural exhibition in 1887. The Council felt, however, that the financial responsi-

bility of such an undertaking would be too great unless it was combined with something else. He believed that there was a general feeling that the time named would be a suitable one for an exhibition of the character proposed, as a considerable period had elapsed since one had been held in London, and he thought that if the way could be seen to carrying a scheme into execution, the Society would receive the hearty support of both amateurs and nurserymen throughout the country. It was considered that an exhibition like that named would, if held in the South Kensington Gardens, have to be accompanied by attractions similar to those provided in the three past years, and that this would be outside the Society's province. The idea had not been abandoned, it was only in abeyance, and it was hoped that some plan might yet be devised to permit its realisation.

Referring to the lists of honorary and foreign members, Sir Trevor Lawrence stated that steps had been taken to increase the numbers of these Fellows, with the result that some highly important additions had been made, including many distinguished scientific horticulturists and botanists in various parts of the world. As one of the chief events of the past year, the Orchid Conference demanded a few remarks. It had proved a decided success. The exhibition in number and variety of plants, and the cultural skill indicated by their healthy condition, was such as it would have been impossible to obtain in any other country. The Conference itself was highly satisfactory; the papers read and the discussion which followed were interesting and instructive, but special praise was accorded to the paper on the "Hybridisation of Orchids," read by Mr. H. J. Veitch. Another important gathering, the Pear Conference, had been a similar success in the number of exhibits, and the President thought that such shows were entitled to be considered of national importance. More attention was being directed to the culture of fruit and vegetables as an important portion of the food supply and as a profitable industry. The official report of the Conference was being prepared by Mr. A. F. Barron, and would form a valuable addition to our knowledge of Pears. The Royal Horticultural Society has undertaken to assist the Committee of the Indian and Colonial Exhibition as far as possible by taking charge of Ferns and other plants required to furnish the courts and galleries, and everything was being done to get the plants into the best condition. The Primula Conference, which is to take place next April, was referred to, and it was stated that much interest centred in it, both here and on the continent, and it was confidently expected to prove a success. As to the nomenclature of Orchids, a subject which had been left over from last year, nothing had been done at present. The existing system was known to be faulty, but it was difficult to suggest a remedy. In the opinion of Sir Trevor Lawrence the first steps to be taken should be in the direction of expunging proper names; he considered it a mistake to associate the names of persons with Orchids.

The President next adverted to what he said was a matter of great importance—namely, the position of the Society at South Kensington. It was becoming more and more evident that it will not be possible to continue as at present. The Exhibition for this year was considered to be the last of the series, and nothing had been arranged for next year, neither was there any definite plan for the disposal of the gardens, but it was quite possible that in a few years they would be built upon. The position held by the Royal Horticultural Society could not be considered as a dignified one, but it was evident that the interest in horticulture was increasing, and that in no part of the world is so much done in its behalf as in Great Britain. The Society had done good work, and he (the President) had no doubt that if they could see the way to establishing themselves upon an independent footing they would be supported in a creditable manner by the horticulturists of this country. No doubt the vitality of the Society will enable them to overcome all the difficulties due to their connection with South Kensington, for at no period of the Society's existence had there been a larger number of gentlemen upon the Council interested in scientific and practical horticulture. In conclusion, Sir Trevor Lawrence remarked that it had been arranged to hold a provincial show at Liverpool this year, they had received an invitation from the Mayor and Corporation, and the Botanic Garden was to be placed at their disposal for the purpose. There was every reason to believe that it would be a great success.

This concluding statement was received with considerable applause, and it is evident that the holding of provincial shows gives general satisfaction. Mr. Liggins inquired why an Assistant-Secretary had been appointed after it had been stated at the last General Meeting that the funds were too low for the purpose. In reply, Sir Trevor Lawrence observed that the course had been adopted because it was found that the work was accumulating too rapidly to be disposed of by the Honorary Secretary, and the greater portion of the salary had been subscribed by the members of the Council and friends, thus enabling the work to be cleared up without materially increasing the Society's expenses.

Mr. Wolley Dod moved the adoption of the Report in a few appropriate words, and in seconding it Mr. Johnson referred in laudatory terms to the excellent work performed at Chiswick. He regretted that it was not more generally known, as he felt sure that if it were the Society would take a higher position. He suggested monthly reports of the work done in the Garden, and thought that more persons might be induced to visit it.

The President then read the results of the ballot as already given, and proposed that the thanks of the meeting be conveyed to the Auditors for their services; also to Major F. Mason, on his retirement from the secretaryship, for the valuable assistance he had rendered them, both propositions being carried unanimously. He also paid some well deserved compliments to Mr. A. F. Barron. He considered he was the right man in the right place, and that it was impossible to overrate his labours in behalf of the Society.

Major Lendy proposed that a Committee be appointed to draw up some plans for the future. In reply to which the President remarked that the Council would consider the matter, and when they had come to some decision they would call a meeting, and that would answer the same purpose as the Committee Major Lendy suggested. A few other observations were made by Fellows present, one commenting rather strongly on the injustice of rendering tickets non-transferable, and Mr. Smee thought that the Society should get clear of the Commissioners as soon as possible. Certain Fellows who have not paid their subscriptions were then formally removed by vote, and a hearty unanimous vote of thanks to the Chairman, proposed by Professor Foster and seconded by Mr. Cheal, brought the proceedings to a close.

## ANNUAL REPORT FOR 1885.

The accounts and balance sheet are submitted to the Fellows in the usual form.

The Council have engaged in protracted negotiations with the Royal Commissioners of the Colonial and Indian Exhibition with the view of obtaining the same terms of admission as were enjoyed by the Fellows during previous exhibitions. They regret to state that the Royal Commissioners, having finally referred the matter to their Finance Committee, have felt themselves unable to grant these terms. The terms finally agreed upon with the Royal Commissioners are the following, viz. :—

40 Guineas Life and 4 Guineas Annual Fellows receive Two Non-transferable Tickets each, and One Book of 40 Orders; 20 Guineas Life and 2 Guineas Annual Fellows receive One Non-transferable Ticket each, and One Book of 20 Orders. The tickets will admit to the Exhibition free of charge whenever open to the public, except on the opening day, the closing day, and on any special occasions which the Royal Commissioners may wish to reserve; on which occasions the holders of these tickets will be able to enter the Exhibition on payment of half the admission for the day. 10 Guineas Life Fellows and 1 Guinea Members receive One Non-transferable Ticket each.

The above terms differ from those of previous years in the fact that the tickets are not transferable.

The Council have had under consideration the practicability of holding a Great International Horticultural Exhibition and Conference in 1887. After two meetings, largely attended by prominent horticulturists, they entered into communication with the Royal Commissioners of the Exhibition of 1884. They regret to state that the encouragement the Commissioners felt able to hold out to them was not sufficient to justify them in undertaking so large a responsibility, especially in view of the very serious financial obligations such an exhibition would necessarily entail. The Council are unanimously of opinion that the time has come for such an International Exhibition, which would, they have reason to believe, be supported by amateur and professional horticulturists in all parts of the kingdom, and they are anxious that the subject should not be lost sight of by the Royal Horticultural Society.

The Council propose to resume the provincial shows which have, in past years, been of use in stimulating local interest in horticulture, in several important centres of population. They hope shortly to conclude arrangements for holding a show in the summer at Liverpool.

Major Mason vacates the office of Secretary under the provisions of the Charter, and does not offer himself for re-election. The Council wish to record their sense of the great service which he has, at much personal inconvenience, rendered to the Society during the time he has held his office. They recommend Mr. William Lee of Downside as his successor.

The thanks of the Society are due to Sir Henry W. Peck, Bart., for his liberal donation of £20 for prizes for Marguerites.

The Council regret to record that Dr. Maxwell Masters, F.R.S., has resigned the post of Foreign Secretary, the duties of which he has discharged for some years with signal success, and to the eminent advantage of the Society.

The Orchid Conference held in May last, at South Kensington, fully realised the expectations of the Council. The plants exhibited were numerous, and many of them of great rarity and beauty. Several papers of great interest, including three communications from Professor Reichenbach, and a valuable memoir on the Hybridisation of Orchids by Mr. H. Veitch, based on original observations, were read, and important discussions took place. A general report of the Conference, with special horticultural and botanical reports on the plants shown, by Mr. Burbidge and Mr. Ridley respectively, is in the hands of the printer, and will shortly be obtainable by Fellows on application to the Secretary.

A Pear Conference was held in the Chiswick Gardens, from the 21st October to the 4th November. About 7000 dishes of fruit, sent from nearly every part of England, were shown, and opportunities were afforded for comparison, correction of nomenclature, and the mutual exchange of information between the growers and others especially interested. The unfavourable weather interfered considerably with the attendance of the general public, but in no way impaired the usefulness of the Conference. A full report, with the result of the labours of the Conference Committee, is being prepared by Mr. Barron.

A Primula Conference will be held on the 20th and 21st April. This has already attracted the attention of Primula growers abroad and at home, and will form an interesting feature in the Society's work.

The Scientific, Fruit, and Floral Committees at South Kensington carried on their labours as usual during the year. The Society is indebted to them for much valuable work. The number of first-class certificates awarded was 288, of which 59 were for Orchids, which seem to be rapidly increasing in popularity.

A most interesting exhibition of Daffodils was held on April 14th, when further discussion on questions relating to Narcissus took place, and the report of the Committee of the Conference held in 1884 was adopted.

The exhibitions in the conservatory during the Inventions Exhibition were of a very high class, especially those of fruits and vegetables, and proved a great attraction to the visitors.

The Council have to thank many of the Fellows for their exhibition of valuable plants at the various meetings; especially Mr. Ware of Tottenham, for his continuous and attractive display of cut hardy flowers during the entire season.

The practical work of the Society at Chiswick has been satisfactorily conducted, and the Gardens maintained in their usual high state of efficiency.

The trials by the several Committees have given good results. Those of the Fruit Committee comprised Potatoes, 200 varieties; Peas, 72 varieties; Cauliflowers and Strawberries; in each of which classes several certificates were awarded. Those of the Floral Committee embraced Fuchsias, 180 varieties; new Pelargoniums, Single Dahlias, Begonias, Carnations and Picotees (of which the Society possesses a large collection), and Ivies, of which 80 varieties are now planted against the walls of the Gardens.

Facilities were again afforded to the International Potato Exhibition Committee for testing new varieties of Potatoes.

The experiments instituted by the Scientific Committee for the prevention of the Potato disease, by what is termed the Jensenian system, were continued, and an interesting report has been prepared by Dr. Masters.

Experiments have been instituted at Chiswick by the Narcissus Committee on the doubling of common Narcissus (pseudo Narcissus), and for the purpose of determining points of nomenclature.

It is proposed during the present season to continue trials by the Fruit and Vegetable Committee of the newer varieties of Peas, Potatoes, Cabbages, and Strawberries; and by the Floral Committee, of Fuchsias, Ivy-leaved and Zonal Pelargoniums, Carnations and Hardy Annuals. The making of a complete collection of the different varieties of Holly is under consideration.

The crops of Grapes and other Fruits were generally good. The Council hope that in future Fellows will avail themselves more extensively of their privilege of purchasing first-class Grapes at prices far below those of the market.

The collection of Apples and Pears in the Gardens having now been proved and their merits recorded, worthless varieties have been discarded.

Applications from Fellows for plants, seeds, and cuttings continue to increase. During the year, 1110 Fellows were supplied with 22,180 plants, 40,000 packets of seeds, and nearly 10,000 cuttings of Vines and other fruit trees.

At the request of various Colonial Governments the Society has received and taken charge of large consignments of Tree Ferns and other plants from Victoria, South Australia, New Zealand, Ceylon, and the West Indies, intended to be shown at the forthcoming Exhibition. These plants occupy a considerable space in the Chiswick Gardens, and have necessitated the heating of the large Rose house for their accommodation. As many of them may not be sufficiently established to be exhibited, Fellows of the Society who may have large spare plants representative of the Flora of any of these countries, are invited to place them at the disposal of the Society for the purposes of the Exhibition.

An exhibition of flowers held by the Chiswick Horticultural Society in the Gardens on July 16th, proved very attractive and a source of interest to the Fellows in the district.

Donations of plants and seeds have been received, amongst others, from the Royal Gardens, Kew; Colonel R. Trevor Clarke; Sir Ferdinand Von Müller, Melbourne; Dr. Schomburgk, Adelaide; Dr. Masters, Messrs. Veitch and Sons, Messrs. Cannell & Sons, Messrs. Barr & Son, Mr. C. Turner, and Mr. John Fraser, to whom the thanks of the Society are due.

The thanks of the Society are due to the Auditors, Messrs. John Lee, Jas. F. West, and W. Richards, who have discharged, gratuitously and with efficiency and dispatch, the arduous duty of auditing their accounts.

During the year twenty-nine Life Fellows and twenty-nine Annual Fellows died; sixty-three Fellows retired from the Society, and 239 new Fellows were elected.

## AUDITORS' REPORT.

To the Council of the Royal Horticultural Society.

Gentlemen,—We beg to report our having audited the accounts of the Society for the past year, and we have compared the vouchers with the books, and found them correct.

We regret to announce that the revenue of the year shows a deficiency of £120.

The Auditors take the opportunity of calling especial attention to the accurate manner in which the books are kept by Mr. J. Douglas Dick.

We have the honour to remain,  
Gentlemen,

Your most obedient Servants,  
JOHN LEE,  
JAS. F. WEST, } Auditors.  
W. RICHARDS,

January 27th, 1886.

## THE DINNER.

In the evening the Council and several members of the Society and friends, to the number of about fifty, sat down to an elegant dinner, provided by Messrs. Spiers & Pond, at the Criterion, Piccadilly, Sir Trevor Lawrence, Bart., M.P., President of the Society, ably presiding. The number of guests would probably have been greater but for the somewhat hurried manner in which the arrangements were made, and there can be little doubt, when the agreeable nature of these annual social gatherings becomes more widely known that they will be correspondingly popular and largely attended. Amongst the company we observed Mr. Mitford, C.B., of the Board of Works, Mr. Thistleton Dyer (Kew), Professor Foster, Mr. Bateman, F.R.S., Dr. Allman, Mr. Baker (Kew), Mr. Harvey (Liverpool), Dr. Duke (Lewisham), Mr. Crowley (Croydon), Rev. W. Ewbank, Dr. Hogg, Mr. Veitch, Mr. Barr, Mr. Bunyard, Mr. Matthews, &c.

After the usual loyal toasts were proposed in graceful terms by the President and duly honoured by the assembly, Mr. Dyer, in an admirable speech, which was listened to with the most attentive appreciation, proposed "Prosperity to the Royal Horticultural Society." He adverted to the deep interest be felt in the welfare of the Society as the representative head of horticulture in the kingdom, to the great and increasing public taste in the cultivation of plants that is apparent, to the unique position occupied by this country as a mercantile nation, in the introduction of plants from distant shores all over the world, to the high and finished examples of culture to be seen in Great Britain, and the importance of maintaining this excellence; he also pointed out that the Council of the Royal Horticultural Society was representative and comprehensive, that the "new departure" in the annual dinner could not fail to have a most wholesome influence in promoting kindly feeling and mutual trust between Fellows and officials, then by unity of

effort the Society would exert a great influence in the future, as it had within its grasp all that was great, dignified, and beautiful, and with the new impulse given that day it would be more firmly established as the custodian of the great industry it was established to promote, and he cordially wished it prosperity. Mr. Dyer's truly excellent address was received with much applause.

Mr. Mitford, in proposing success to horticulture, referred to the recent appointment of Mr. Dyer, who, he had not a doubt, was from every point of view the proper man to succeed Sir Joseph Hooker; he referred to the two generations of Hookers who had conducted the affairs of Kew so ably, and the Board of Trade wished there had been a third; but the next best successor they were certain was found in Mr. Dyer, an appointment that had given the greatest satisfaction. As he (Mr. Mitford) was not a cultivator, he thought it would be wisest to say but little on that subject, but to confine himself to the expression of his pleasure in being present, and his earnest hope that horticulture might flourish.

Mr. Harvey, in responding, observed that if the Royal Horticultural Society intended to be truly national it must go to the provinces—to the north. He asked the company to look at Scotchmen to see what they had done, and to Lancashire with its ungenial climate, and note the progress there. The worse the climate, he thought, the greater the love of gardens, because of the pride that appeared to be taken in overcoming difficulties. Liverpool had done, and was doing, something for horticulture, and would do more. Many Orchids had been imported there, and Cattleya Mossiae was named after a Liverpool lady. Speaking for the north, he said they could do very well without any Orchid Society, and hoped he should not see one, but would rather see special committees appointed by the Royal Horticultural Society to devote attention to separate branches of horticulture. Mr. Harvey's remarks appeared to meet with warm and very general support.

Professor Foster, in proposing "Our Guests," appropriately quoted the line "Words flow apace if you wish to complain." This was in reference to complaints in the press, an amusing instance of which he had seen in the proposition for an Orchid Society, one writer advocating it on the ground that the Royal Horticultural Society does not adequately attend to these plants; another because the Society is favourably disposed to promoting their culture. But referring to the guests, with Mr. Ewbank on his left and Mr. Baker on his right, words did not flow apace when he desired to express the pleasure the Council had in their company. Mr. Ewbank he described as a horticultural phenomenon, because he made everything grow in his garden in which he took such great delight, and he could think of no more appropriate description of him than a "happy gardener." Mr. Baker was also a phenomenon in his capacity for naming plants. Ten thousand names, he had been told, was as many as could be stored in one brain; still, with his wonderful aptitude, Mr. Baker was striving to reduce names. Such men as their guests were wanted as Fellows. The Royal Horticultural Society had for some years adopted a wrong system. They had gone in for numbers, regardless as to what proportion were horticulturists. He hoped they would start fresh from to-day and soon get from South Kensington, live no longer a parasitic life, but strike root for themselves and not live on the juice of others. They wanted a room for their meetings with ready access to the incomparable Lindley library, and surely that could be found. To return to the "guests." As he had named two, and could only ask one to respond, he decided by a toss, and must call on his right hand friend.

Mr. Baker, who met with a warm reception, observed that on-lookers could often see the most of the game. He could see how important it was for botanists and horticulturists to go hand in hand. Dried plants were not always satisfactory for purposes of nomenclature, as new introductions were constantly arriving they required to be grown. He observed that it would be a shame for England if the Royal Horticultural Society should fall into an inferior position now that the interest in gardening was greater than ever it was before. Regarding plant names, he observed that while botanists were trying to reduce them, horticulturists, and particularly specialists rushed along in their own way, manufacturing names without any systematic classification. If there were twenty Daffodils, for instance, there appeared to be a disposition to magnify them into 500, and the same with Primulas. He would like to see the Royal Horticultural Society in the position of interpreter, standing between gardeners and botanists, yet embracing both, and he trusted the Society would have a great and useful future career.

Mr. Bateman, in rising to propose the health of the President, referred to him not only as the chief of the Society, but chief over a great family of plants—Orchids, which Rumphius had described as a "Royal Race." He graphically described the discovery of Cattleya Lawrenceana; and adverted to plant names, observed that twenty-two years ago a charming Princess came to this country and a charming Odontoglossum flowered at the same time, which he, as a loyal subject, named Alexandræ. He was found faint with; but if he erred so did Reichenbach, who called it Bluntii. It may be a variety of O. crispum; but why, since the variety is so distinct, not adhere to the distinctive name and call a beautiful plant after a beautiful lady? The name Wellingtonia is wrong. It should be Sequoia; but the country would go to war rather than lose the familiar name, and he would go to war for Alexandræ—crispum appearing as if it had reference to an old woman in the reign of Queen Elizabeth. There were stated to be 6000 distinct Orchids in cultivation, and if they increased to 10,000 he wished the President to see all his subjects and be able to call them all by their names.

Sir Trevor Lawrence, in responding, alluded to the freshness and healthy flavour of the speeches and the Society, remarking that he was supported in his position by gentlemen who would add lustre to any institution. He hoped the parasitic existence that had been alluded to would terminate, believing there are plenty of real horticulturists in the country to support the Society. He agreed with Mr. Harvey that an Orchid Society is not needed; indeed, he did not believe in frittering in a number of special societies. He was convinced the Royal Horticultural Society has a good future in store, and expected a genuine response in holding a provincial Show at Liverpool. He trusted there would be no real difficulty in finding a new home for the Society; the difficulty was in finding a place for periodical meetings and shows. Yet with a hearty and single-minded purpose to represent the interests of horticulture in this country, difficulties will vanish and a home will be found.

Mr. Veitch proposed the toast of the "Amateurs," and in doing so re-

gretted the absence of several of his brother nurserymen. However, in their names and his own he desired to recognise the valuable support given to horticulture by the many gentlemen who delight in their gardens, and who furnish them in a befitting manner. He desired also to make a suggestion to the Council of the Royal Horticultural Society, and would ask them to not forget the existence of nurserymen and practical gardeners. He thought it would not be inappropriate for both the classes named to be directly represented on the Council, as in past time, when the Society was at least as flourishing as it is now. He had often heard his father say that when any practical matter was under discussion, and the late Prince Consort presided, his Royal Highness always turned to the practical men for an expression of their opinion.

Dr. Allman, in responding, said the pleasure derivable from gardening and the cultivation of plants no one knew who had not experienced it. Every moment added to their delight, and fresh joys were ever arising. It was pleasant to bring plants from other lands and localities and establish them in positions where they can be enjoyed. He wished success to all who were engaged in the delightful pursuit to which they had devoted themselves.

A vote of thanks was cordially proposed to Mr. Lee, the newly appointed Secretary, for his services in regard to the dinner, and in other ways. This gentleman, in briefly responding, said it was their intention to carry out every good practical suggestion, and to place the Society in a position to enjoy the confidence of all horticulturists in the kingdom. The proceedings of a very successful and enjoyable evening then terminated.

## THE PRIMULAS.

(Continued from page 573.)

**P. MOLLIS, Nutt.**—The soft-leaved Bhotan Primrose is included by many botanists under the large section "*Primulastrum*," but we prefer for simplicity M. Stein's plan of classing it in "*Cortusina*, *Schott*," in company with *P. cortusoides* and its forms and the new *P. Kauffmanniana*, *Regel*. The latter classification seems the best as far as affinity goes, besides being much more convenient for cultivators. *P. mollis* is one of those Primroses which it is almost hopeless to attempt cultivating in the open air in this country—not so much from the cold, as we believe it is found at fairly high elevations, but from damp, caused by fog, &c. We have tried it in the neighbourhood of London under almost all the conditions conceivable, sometimes with apparent success, but which invariably ended in failure. Even under glasses and overhanging ledges it was found to have decayed. We winter it successfully in a dry cool frame, airing freely on bright days and watering only when very dry, and even then care is required to keep the water from lodging about the woolly crown. We succeed with it best in pots, having given up planting it out, and as it is a quick coarse grower it requires plenty of pot room and plenty of feeding. It makes a charming greenhouse plant when well grown, and it not uncommonly produces from twenty to thirty flower stems, each averaging from four to five whorls of its large bright flowers, presenting with the densely hairy foliage a really magnificent sight. If flowered early in good seasons it produces seed, but it may also be readily propagated by division of the crowns in winter. The foliage all rise from the root, the leaves on long petioles entirely covered with curious spreading hairs, the blade almost round in outline with a cordate base, and lobed and crenated margins, veined or reticulated. The flower stems vary from 12 to 18 inches in height, the flowers being arranged in whorls; the corollas about an inch in diameter, of a bright rose or brick-red colour; the petals deeply lobed; the calyx campanulate, hairy; the teeth short and broad at the base. It flowers from April until the end of July. It was found in the Bhotan Mountains by Mr. Booth about 1852.

**P. MURETIANA, Moritizi.**—A hybrid between *P. subintegrifolia* × *viscosa*, *A. Kern*. It is closely allied to *P. Dinyana*, which is superintegrifolia, and easier to grow than the latter hybrid. It is also more robust in habit, having a larger share of *viscosa*. This plant seems to show more clearly than any we have yet described that hybrids are more vigorous than their parents; and although, as may be seen, it possesses more of *integrifolia* than *viscosa*, yet the plants equal if not surpass the later vigour, raising the lowly *integrifolia* to a striking plant. It requires deep, rich, but light well-drained soil to grow it well, and apparently taking best to a western exposure. We grow it on steep slopes with only a few stones round the base of the stems, they serving the double purpose of keeping the surface roots cool, and just retaining sufficient moisture for the plants. The whole plant seldom reaches more than half a foot in height, the leaves nearly those of *P. viscosa*, with fewer and shorter hairs and more dilated at the base. Flowers large, of a deep rich purple, opening earlier than *integrifolia*. Plentiful on the high Alps. Syn., *P. Mureti*, *Rech*.

**P. NELSONI, Hort.**—Another Primrose I have not seen, and only mention it in the hope that it may appear from some obscure corner, as M. Stein says he has only seen it once at Innsbruck, whence it was received from London, and according to English cata-

logues it can only be a form of the *P. villosa* group with pale flowers.

**P. NIVALIS, Pall.**, is a very distinct plant from the one we generally find in gardens under that name, the latter being only a white variety of the European *P. viscosa*, and may perhaps be a corruption of *nivea* or *niveus*, a name by which the variety is known in the trade. *P. luteola* is another plant sometimes sent out under the above name, and although when out of flower there is some affinity. The flowers are so very different that when seen all doubt is dispersed as to which it is. Six or more years ago *P. nivalis* was in cultivation in our gardens, and the admiration expressed concerning it at that time falls to the lot of few Primroses, and yet at the present time, when so much interest is being raised in their favour, this remarkable plant is hardly to be found. It seems more adapted for general cultivation than any other of our Alpine species, for not only is it extremely variable both in form and colour, but it is perfectly hardy and may be cultivated in an ordinary border with comparatively little trouble. Its variable nature suggests, under cultivation, quite a new race of Primulas, more especially if it be found amenable to the ingenuity of the hybridiser. In the "*Gartenflora*" Dr. Regel gives a very interesting history of this plant, part of which I append. *P. nivalis* proper, not including the two nearly allied forms—*i.e.*, *longifolia* and *turkestanica* varieties, is undoubtedly one of the most beautiful species of the genus. From the high mountains of the Caucasus it is distributed northwards to Altai and the mountains of Transbaicalia, as well as to Eastern Siberia, Kamtschatka, and N.W. America. Southward it is spread all over the mountains of the provinces of Turkestan, as well as the Alps of Afghanistan and Nepal. It was re-introduced by Regel and Tetison from the Alps of Thian-Shan and flowered in the St. Petersburg Botanic Garden. It has in its wild state produced several different forms, by the introduction of which our collection can be considerably augmented. Thus we have dwarf varieties and tall-growing ones, with broader leaves, glabrous forms, and others with a dense coat of white powder either on the under or on both sides of the leaves, on the petioles and also on the calyx; the flowers being either arranged in one whorl or in two or more in robust specimens, the colour ranging from rose to dark violet purple, the corolla tube varying from the same to twice the length of the calyx. As a guide to its cultivation it is found growing with the following plants, and in gardens where they succeed there will be found little difficulty with this noble Primrose. *Potentilla fruticosa*, *Caragana jubata*, and at the base of the large snow fields at 11,000 feet we found *Callianthemum rutifolium* and *Carex atrata*, and even at 11,500 feet traced specimens of *P. nivalis*.

It grows about 18 inches in height, many flowers in a whorl, reddish or rose-coloured in typical plants, but, as before stated, variable. The leaves are distinct, and may be recognised by the margins always being curled or turned inwards, and also in the purplish tinge of the midrib, especially towards the base. It flowers with us from May onwards. The variety *turkestanica* has very deep violet flowers and elliptic lanceolate leaves more deeply crenated at the edges than the type. Syn., *P. nivalis* var. *colorata*. *P. longifolia* has longer and altogether narrower leaves than either, with rosy flowers.

**P. OBOVATA, Huter.**—An interesting hybrid. *P. Balbisii* × *tyrolensis*, *A. Kern*. I believe to be in cultivation, although I have never seen it alive.

**P. OBRISTII, Stein**; super-*Balbisii* × *Auricula*, *Stein*.—This is too near *P. Balbisii*, as far as we have yet seen in the young plants, to warrant a detailed account. It is, however, more robust than *P. Balbisii*, and flourishes equally well on the rockery in a rather exposed situation.

**P. OBTUSIFOLIA, Royle.**—Under this name seeds were freely distributed two or three years ago, but afterwards it was found to be a form of *P. involucrata*. It is, however, quite distinct from the latter, and more nearly resembles forms or states of *P. Stuarti*, from which it may be distinguished by the thin texture of the leaves and the round capsule. It is a very variable plant, however, and extreme forms, such as the one with the deeply toothed obovate leaves, appear quite distinct from the one with the spatulate leaves. It grows about a foot in height, the leaves having distinctly winged petioles, and generally covered with yellow meal beneath. Flowers collected in a loose capitate head an inch or more in diameter, of a bright blue purple with a fine yellow eye. Flowers about July. It seems partial to peaty soil in a cool shady situation, and likes plenty of moisture during the growing season. It is perfectly hardy, and no fear need be felt about planting it out. It is found in the East and West Himalayas, Kunawar, Kumaon, and in Sikkim at elevations at 11,000 to 12,000 feet above the sea, also in Bhotan. The varieties *Roylei* and *Griffithi* are both distinct, although no advance on the type as garden plants.—D.

## THE PERCIVAL COLLECTION OF ORCHIDS.

At present it is very difficult to obtain a complete list of those who purchased the principal plants of this collection, as all the officials of the Liverpool Horticultural Company are still kept very busy, as may be expected. Many of the most noteworthy plants were sold for the prices named in the catalogue, as referred to last week on page 86. The principal plants for which there were several would-be buyers were sold during the afternoon of the 3rd inst. Some of the particulars may be interesting.

Amongst *Ceologyne* two only will be mentioned, and both passed into the hands of Messrs. Sander of St. Albans, for seventeen and eleven guineas respectively. The plant for the first contained about 200 pseudo-bulbs in an 18-inch pan, and was the Chatsworth variety of *C. cristata*. The latter was in a pan 30 inches in diameter, and rising 16 inches in the centre. The catalogue price for these two was ten and eight guineas in the order named. The only particulars obtained of *Laelia anceps* was of a plant of *L. anceps* Percivaliana with thirty-eight pseudo-bulbs and eight flower spikes, which passed into the hands of Mr. B. S. Williams, Victoria and Paradise Nursery, Upper Holloway, London, for forty-seven guineas, being seven guineas more than the reserve price. *Cypripedium insigne* punctatum violaceum with twenty growths was purchased by Messrs. Sander & Co. for twenty guineas. Mr. J. Cypher, Cheltenham, secured smaller plants with half the number of growths for ten guineas. Messrs. Sander & Co. bought *Cypripedium Dominianum* with fifteen growths for ten guineas.

The competition for some of the *Cattleyas* was considerable. One plant of *C. Mossiae*, with 120 pseudo-bulbs and eighteen flower sheaths, was purchased for ten guineas by the Right Hon. Joseph Chamberlain, M.P., Birmingham. This was said to be a fine variety, and the catalogue price was three guineas less. Another plant of the same variety, with 170 pseudo-bulbs, has gone into the collection of H. Gaskell, Esq., Woolton Wood, Liverpool, for ten and a half guineas, being more than double the catalogue price. The same gentleman bought two other plants, one with 106 pseudo-bulbs and sixteen flowers, and another with 140 and nineteen flower sheaths, for twelve and a half and ten guineas respectively. Also two other plants of the same variety with sixty pseudo-bulbs and twelve flower sheaths, and the other with forty-nine of the former and the same number of the latter, for eleven and ten guineas in the order named, the catalogue price for each being four guineas. Two plants of *C. Mossiae* Arnoldiana, one with seventy pseudo-bulbs and ten flower sheaths, and the other with twenty-three of the former and three of the latter, became the property of Sir Trevor Lawrence, Dorking, Surrey, for the sums of thirty-two and sixteen and a half guineas, being twenty and a half guineas more for the two plants than the reserve price. The same gentleman became the owner of three very fine plants of *C. Percivaliana*, one with forty-three pseudo-bulbs and nine flower sheaths, another with twenty-one of the former and three of the latter, and the third with thirty-six and nine respectively, for the sums of twenty-seven, thirteen and a half, and eighty guineas. The flowers of the last plant were figured in the "Orchid Album," vol. 3, plate 144. The catalogue prices for the three plants being, in the order referred to, twenty, ten, and fifty guineas each. Mr. Gaskell purchased another plant of this variety with twenty pseudo-bulbs and two flower sheaths, said to be *A1* by Mr. Percival, for fifteen and a half guineas. Messrs. Sander & Co. became the owner of *C. Percivaliana* alba (Reich) with ten pseudo-bulbs and two flower sheaths for the sum of twenty guineas, also a second with nine bulbs and one flower sheath, for fifteen guineas. A plant of *C. Skinneri*, with 140 pseudo-bulbs and twenty-six flower sheaths, passed into the same hands for thirty-two guineas, as well as *C. oculata* with twenty-eight flower sheaths for forty guineas.

Sir Trevor Lawrence obtained three plants of *C. Mendelii* for 70, 48, and 38 guineas, the first plant having twenty flower sheaths, the second twelve, and the third five. Enoch Harvey, Esq., Riversdale, Aigburth, obtained another with forty-four pseudo-bulbs and five flower sheaths, said to be a very fine variety, for forty-eight guineas. Mr. Gaskell a dark variety for 34 guineas, having sixty pseudo-bulbs and ten flower sheaths. A superior variety of *C. Mendelii* aurea passed into the hands of F. Hunt, Esq., Stamford Hill, London, for 22½ guineas. This plant had twenty-eight pseudo-bulbs. A plant of *C. exoniensis* with two leads passed into the hands of A. Wilson, Esq., Westbrook, Sheffield, for 17½ guineas. The plant of *C. Brymerianum*, with twelve pseudo-bulbs and two leads (figured in the "Orchid Album," vol. iv., plate 184) for the sum of 49 guineas, the catalogue price being 25 guineas. *C. Mossiae* Hardyana, with ten pseudo-bulbs and two leads (also figured in the "Orchid Album," vol. iii., plate 145), passed, as well as the above plant, into the Woolton Wood collection for 49 guineas. A plant of *C. Sanderiana*, with seventy-five pseudo-bulbs, 38 guineas; also *C. gigas*, in a basket, with thirty-three pseudo-bulbs, went to the same collection for 13 guineas. Another plant of the same variety, with sixteen pseudo-bulbs, was purchased by C. W. Scott, Esq., Woodbank, Dumfries, for 16 guineas, the catalogue price being less than one-half. Two plants of *C. Trianae* formosa were purchased by Mr. Gaskell for 29 and 20 guineas, the first having seven flower sheaths and the latter three. The same gentleman also obtained the plant of *C. T. Normanii* for 20 guineas, with three flower sheaths and fifty pseudo-bulbs. Sir T. Lawrence also secured a plant of this variety, slightly smaller, but with double the number of flower sheaths, for 15½ guineas. A plant of *C. Trianae*, with twenty-eight pseudo-bulbs and six flower sheaths, passed into the hands of D. de Yvrandou, Ullet Road, Liverpool, for 10½ guineas.

*Dendrobium Jameianum*, with eight new pseudo-bulbs and forty-four old ones has gone to St. Albans for the sum of 13½ guineas. A plant of

*Odontoglossum guttatum*, with six pseudo-bulbs and one lead, said to be a very fine variety, has been added to the Woolton collection for 16 guineas, being more than three times the catalogue price.

Messrs. Sander & Co. obtained a fine plant of *Laelia purpurata* alba, with 113 pseudo-bulbs and fourteen flower sheaths, for 50 guineas; Mr. Gaskell another having nearly the same number of pseudo-bulbs, ten leads and six sheaths for the sum of 40 guineas; Mr. B. S. Williams a third, with fifteen leads and four sheaths, for 10 guineas less than the last named price. The same purchaser also obtained *L. elegans* prasiata, with four leads, for 25 guineas; Mr. Gaskell *L. elegans* alba, with the same number of leads, said to be a grand variety, for 50 guineas. *L. Phalaenopsis* Schilleriana, with nine large leaves and one flower spike was secured by Mr. Gaskell for 16 guineas; also to other plants, with seven and six leaves, for the sums of 10 and 11 guineas respectively. *Vanda Sanderiana*, with two leads and three or four pairs of leaves, was purchased by the same gentleman for 10½ guineas.

Enough has been given to show that the zeal for special varieties has not abated since the importation of these plants in such vast numbers, and their disposal in consequence at comparatively low prices. The prices given for some, as will be seen, considerably exceeded the catalogue prices, in fact about £500 more was realised by those sold by auction. This amount would have been considerably exceeded but for the specifications of sale, which prevented all who had not previously ordered from bidding.—WM. BARDNEY.

## ECONOMY IN THE ARRANGEMENT OF CUT FLOWERS.

GENERALLY speaking, gardeners who have to produce flowers for cutting have some idea of economy in using them. They will take care to grow such flowers as will remain fresh when cut for a fair length of time, and in re-arranging due care will be taken of such flowers as may be found fresh enough to be used again. But from a variety of reasons the gardeners in a great many of the smaller establishments are not called upon to arrange cut flowers. Often—and very properly—the lady of the house has plenty of time, has a taste for, and likes to arrange cut flowers herself. Others, as they find the cares and anxieties of the household and other social duties increase upon them, will give it into the hands of a "lady-help," or a handy lady's maid, with the good intention of saving the time of the gardener. The gardener has generally enough to occupy his attention and will seldom grumble at this arrangement, if those who are entrusted with it are reasonable in their demands and show some regard to economy in their style of arrangements when flowers are not very plentiful. Unfortunately this is not always the case. Sometimes the demands are insatiable, and as soon as a few flowers begin to fall or look faded they are bundled out, fresh and faded together. During summer, when flowers are plentiful and do not last so long fresh in a cut state, this is perhaps the best thing to do; but during the dull months of winter many gardeners have not the means of forcing large quantities of flowers, and for such to witness the waste of flowers practised by those who arrange them is grieving in the extreme.

Another thing gardeners have often to complain of is the enormous quantity of flowers some of these amateur decorators will cram into a very small space. They take an epergne or vase just as it is, with a little water in it, and though they find it difficult to get the flowers to stand in the position they would like, yet they have not the ingenuity to perceive or are too indifferent to take such steps as would facilitate their task. They simply go on sticking in more flowers so that the one supports the other, the general result being a crowded mass instead of a light and elegant arrangement. It would be well for ladies who do not personally see to the arrangement of cut flowers to leave it in the hands of their gardener, who will generally contrive to find time, and will be more satisfied with the result of his labour.

I have now jotted down a few hints which may be useful to some of your readers who may not have had much experience in this matter; and let us hope that as they improve in the matter of economy they may in the same degree advance in taste and style of arrangement. Epergnes are rather difficult to deal with, chiefly on account of the extremely shallow vessels. A good plan is to fill them up with fine sand and cover it over with soft green moss, such as is to be found growing on stumps of trees or moist rocks, and the whole saturated with water; or the sand may be covered with *Selaginella denticulata*, which with care will remain fresh for a considerable time and form a pleasant ground for the flowers. For the base of the epergne nothing is better as a border than the common Maidenhair (*Adiantum cuneatum*). Get good large fronds and arrange them so that the broader part of the fronds rest on the top of the moss all round the outside, only little more than half of it overhanging the edge. In arranging the flowers use such as are cut with very little wood, or none at all—as in the case of *Camellias*—round the outside, so that they may rest on the damp moss. All flowers of a formal character should be first arranged thinly, and then sprays of lighter flowers placed between them in a free and easy manner. Avoid crowding and place nothing in an unnatural position. For instance, it is quite right that we set a truss of a Zonal *Pelargonium* in a prim upright position, but it would be an outrage on Nature to do the same with *Lapagerias*, *Passion Flowers*, or anything that is of a pendant habit. These are seen to better advantage hanging from the upper tiers of the epergne. For a border for these latter something of a creeping or scandent habit is more suitable than Fern fronds. *Selaginella uncinata* and *Lygodium scandens* are two useful plants for this purpose.

To facilitate the filling of large china bowls (sometimes used) or

haskets, a piece of small-mesh wire net should be cut so that it will rest on the surface of the water or a little under it. On this place a layer of moss, which will not only keep the flowers in position, but the moisture rises in the moss as it would in a sponge, and keep the stems and foliage in contact with it fresher than they would be by simply having water in it. The same plan should be adopted with wide-topped vases.

Amateurs who are not skilled in the art of bouquet-making will find a light wire frame, such as that represented in the annexed sketch, useful.

Fig. 20.

Maidenhair Fern all round, putting them through the moss half-way between the centre and circumference, and use a little damp moss in tying the stems together. The flowers may then be put in—the larger ones first—thinly, and smaller sprays and Fern between. The advantage of such a frame to the inexperienced is that tying each flower as it is put in is not necessary, and that it can be stuck into the neck of a bottle or other receptacle, as occasion may require, without displacing any that are not secured.—R. INGLIS.

### SEASONABLE HINTS ON FLORISTS' FLOWERS.

AFTER an experience of winter very unlike that of the last two years it will be perhaps not unreasonable to hope that we have seen the worst of it; for although we do frequently get much cold in February, yet the "days lengthen and the sun strengthens," and we are not so likely to have that damp cold which is most injurious to plants both under protection and out of doors; that which causes softwooded plants to "fog off" in houses and frames, and many of the alpine plants in rockeries to damp off and decay, for they have not that warm covering of snow which keeps them fresh and lively under its protecting mantle. It has been curious to notice when there has been a good fall of snow how, when it has passed away, the Aconites, Hepaticas, Cyclamens, &c., have been progressing under it. But even if we have not seen the bad weather, there must now be activity amongst the growers of florists' flowers. Operations must not longer be deferred, or the hopes of a year may be destroyed.

**Auriculas.**—There is no period of the year at which these look so poor as now. The fine foliage which they had in summer has gone; week after week outer leaves have withered and been removed, leaving, when the plants are healthy, a small solid heart from which the future plant is to be developed. Anyone unacquainted with them would pronounce them now to be miserable weeds. Not so the expert. Give him but a good solid plant, and he knows that in time he will have a luxuriant and flourishing one to show you. A severe winter, provided the frames be well covered, is not injurious to them—rather the reverse. It keeps them back, and does not stimulate them into premature growth and too early flowering. As I have of late said, my observations are not intended for exhibitors, but for those who grow for love's sake, and, therefore, I do not advocate the necessity of keeping back such varieties as Taylor's Glory, Acme, or most of the selfs, which come too early; or forwarding Richard Headley or Hero, which are generally laggards. The grower who is not influenced by the dates of shows will have some enjoyment of his plants. I again last year dispensed with top-dressing, and think my plants were just as well without it, owing to watering, stirring the soil, &c. During some months the soil in the pots gets wasted, and it will be necessary to fill them up when this is the case, using a simple compost of three-parts loam and one part of decayed cow dung. The surface should be well stirred, all signs of decaying leaves removed, and then if necessary fresh compost added. This is very different from the process of top-dressing, which used to be considered absolutely needful, and which was one of the events of the Auricula-grower's year. Great care is also necessary, as the weather becomes less cold, to look out for the green fly, which should be carefully brushed off, or if it be too troublesome the frames or pit may be fumigated with tobacco.

**Carnations and Picotees.**—Those in beds have had rather a rough time of it this year, but with the exception of a few of the yellow ground Picotees mine seem to have weathered it well. The beds will now require examining, and if the plants have been loosened by frost they should be pressed down into the soil. Those in pots have kept singularly clear of spot, and it will soon be time now to prepare for placing them in the blooming pots. Pots should be cleaned, compost turned over and made ready for use, and everything got into a state of forwardness, for a time will soon come when out-of-door work will press heavily on gardeners, and everything of preparation that can be got through should be completed.

**Pansies.**—Transfer these to their largest pots. It is a moot question whether they should be placed in large size 32's or 40's. The former gives more room; but perhaps it will be found that by using smaller pots there is less danger of rotting the roots, while stimulants can be added afterwards. Every year sees the old Show varieties as they were called being elbowed out of the way by the more varied and robust-growing Fancies. The compost to be used must be simple and sweet; that used for Auriculas, with addition of a little leaf mould, will do very well—say three parts loam, one rotted manure, and one leaf mould, with a little coarse sand or road grit to keep it open.

**Ranunculus.**—These ought to be planted very soon. The 12th of February is the day that has been always regarded as the best time for the operation, but of course that depends very much on the state of the ground. At present it is so completely saturated with the heavy rainfall and sun of January that it will be very unlikely that it will be in a fit state for the operation at the orthodox time; still, if a dry time set in we must be prepared for it. See that there are sufficient roots for the beds required, and if not, the sooner the vacancies are filled up the better.

**Gladioli.**—The only thing that can be done with these now is to look through them and see that they are not emitting roots. When they are it is better to pot them into small pots at once without injuring the roots, and to plant from these into beds. It is only, however, where they are placed in bags that this is likely to occur. Where they are laid out on shelves or trays this does not happen. Where it is needful to add to the collection no time is to be lost.—D., Deal.

**WEST AUSTRALIAN TIMBER.**—Western Australia is very rich in good timber, which is now being largely developed. The forests of Western Australia cover an area as large as Great Britain. There are more than 30,000 square miles covered with Eucalyptus, 24,000 miles of which consist of the White Gum (*E. viminalis*) and Jarrah (*E. marginata*). The latter is a most important shipbuilding wood from its imperishable nature and immunity of attack from insects. The Tooart (*E. gomphoccephala*) and Red Gum (*E. calophylla*) are also excellent woods.

### HARDY FRUIT GARDEN.

**PEACHES AND NECTARINES.**—Let the pruning and training of Peaches, Nectarines, and Apricots be done now, so as to have all finished before there is any risk of damage to swelling buds. Apricots answer well under spur-pruning with the branches presenting the appearance of parallel cordons. Avoid spur-pruning for Peaches and Nectarines, stout main branches trained fan-fashion well furnished with lateral fruiting wood of last year's growth, robust and sturdy, as stout as an ordinary cedar pencil, of ruddy brown hue and firm texture, and well set with triple buds. With plenty of such wood we may confidently anticipate a crop of really fine fruit this year, only take good care not to retain too many laterals. Better, far better, is it to tie in fruiting wood thinly than to have it crowded, and subsequently to have much thinning of fruit. If the fruiting wood has a slender attenuated appearance with only single blossom buds the fruit will be small and the wood growth weak. For our part we never retain such wood except in cases of necessity when fruit must be had; but knowing that slender weakly growth is a sure indication of debility, of hardened tissue, of sluggish sap action, we invariably behead the tree, cutting off all the branches to within 2 or 3 feet of the base. The old soil is removed down to the roots and replaced with sound rich loam; a subsequent growth of remarkable vigour usually follows, so that in two or three seasons the whole of the wall space is again covered, and the tree is in full vigour and fruitfulness once more. A gardener requires considerable experience, sound judgment, and some courage ere he can venture upon such bold measures with trees entrusted to his care. It is to strengthen his hands that we write this note, as well as to assure the owner of the trees that they will not be spoiled.

Newly planted trees should always be headed back at the time of planting, our object before all things being to have the trees fully developed and well furnished with fruiting wood as soon as possible. Planted in carefully made well-drained stations of rich loam with the branches all shortened to about 18 inches or 2 feet from the base, the trees start freely and strongly into growth in spring, and if only we can contrive to screen the young foliage from cold cutting north-east winds, and keep the soil about the roots moist, they will sustain no check. Have no fear that the growth will be too robust. We have often had young fan-trained trees cover the greater part of the wall space allotted them in two years; and although the main branches have developed so much wood growth as to be barren of fruit buds, yet they have plenty of stout fruiting laterals. Let it be clearly understood that in the second year it is possible to have a branch growth full 6 feet long with plenty of laterals well set with triple buds, from which a crop of fine fruit may be had in the third year.

### FRUIT FORCING.

**CHERRY HOUSE.**—The temperature having been maintained at 40° to 45°, and about 50° in the daytime regularly, the trees are now rapidly unfolding their buds, and before long the blossom will have a beautiful appearance. Before the flowers expand it will be well to fumigate the house so as to make sure that the trees are free from insects, or an application of clear rather strong quassia water will answer the same purpose, repeating at intervals of a day or two. Any alterations in the way of introducing fresh trees must be completed without delay, and taking precautionary measures, so that shading may be applied to such trees whenever sunshine is powerful; and in order to promote the re-establishment of such trees as quickly as possible they should be lightly sprinkled more frequently, and other surrounding surfaces moistened.

**VINES.**—*Early Vines in Pots.*—When the bunches have been properly thinned the laterals behind them will require moderately close stopping, whilst those beyond or in advance of the fruit may be allowed more freedom provided there is space for their development and being tied down to the trellis. Guard against overcropping, quality being always of more importance than quantity, removing surplus bunches. Top-dress the soil with rich compost and decayed manure, to receive which have rims of zinc or lead 4 inches deep fitting within the rim of the pots, and to insure the passage of water through the pots. If the pots are standing on solid brick pedestals and fermenting materials are placed loosely round the pots, liberal supplies of stimulating liquid may be more frequently given than when they are tightly plunged to the rim, and in all cases where the pots are to remain undisturbed until the Grapes are ripe the roots may be allowed to follow the liquid through the loose brick pedestals and the plunging material, when the fruit will be fine in proportion to the number of feeders that extend beyond the pots.

*Earliest Vines.*—Give close attention to stopping, tying, and thinning, and observe great determination in the removal of surplus bunches before they have time to rob the Vines; a judicious reduction in the number of bunches does not always mean a corresponding reduction in weight when the Grapes are ripe. Allow as much extension above the bunches as the space at command warrants, but only until the space is fairly covered with foliage, then keep the growth closely pinched. Afford liquid manure in a weak and tepid state to the inside borders, and mulch with short manure fresh from the stables to give off ammonia. Close the house early with plenty of atmospheric moisture.

*Early Muscats.*—Where there is a house devoted to these, and assuming it was closed about the middle of December, the bunches are now approaching the flowering stage, and will require a night temperature of 65° to 70°, with a rise of 10° to 15° by day, and the house may be closed at 80° to 85° when bright weather prevails. When they commence flowering it will be necessary to fertilise every bunch with their own or Black Hamburg pollen, and the Muscats so treated usually set well. Early Muscats are much prized, and to have them ripe early or by June they require to be started at the time indicated, as to do them well they require some time in ripening, the wood being thoroughly ripened and the roots having the benefit of a warm inside border, which has been well mulched and the Vines well fed through the previous growing season for the purpose of keeping the roots near the surface instead of driving them down in quest of moisture and nutrition.

*Succession Houses.*—Attend to disbudding and tying. Tie down the young shoots before they touch the glass, and allow the first to extend when it is thought desirable to cover vacant space with foliage. Remove all surplus bunches before they flower, and maintain a moderate moisture even afterwards by damping occasionally, keeping a rather warm atmosphere, but with a gentle circulation of air constantly. If there is any lack of moisture in the borders give a thorough supply before the flowers open.

*Late Houses.*—Assuming that the Vines were cleared of the Grapes early in January, and that the inside borders have been top-dressed with fresh loam and crushed bones, a good supply of tepid water should be given, and a start made without much further delay, as it is essential to the Grapes keeping well that they be ripened thoroughly by the middle of September. Keep the strong rods in a horizontal position, and insure an even break by syringing three times a day. Keep the temperature at 55° by night, rising 5° to 10° by day, and an advance of 5° or more from sun heat.

**PINES.**—*Fermenting Beds.*—Where these are employed as a means of giving heat to the roots of Pines, it is a usual practice to remake them just prior to the approach of winter, and to incorporate the materials employed in such manner as to make the heat generated by them as steady and durable as possible. Under ordinary circumstances these beds will now require similar attention, and should be renewed by fresh material as soon as circumstances permit. This kind of work is generally put off to unfavourable weather for other work, and in this there is nothing wrong provided the work is done at the right time in the proper manner. Opportunities that occur for this kind of work should be taken advantage of, at least it must be attended to, as at the end of this or the beginning of next month some suckers should be started, and the requisite attention given to such plants as require it, as repotting or otherwise shifting into larger pots such as require it, giving timely attention to the preparation of the soil, and other requisites of potting, so as to have all ready when the time arrives. The loam, especially when of a tenacious nature, should be had under cover to become dried.

*Fruiting Plants.*—Strive to insure an invigorating condition to these, giving every attention to the moisture that is needed, and taking every advantage of gleams of sunshine to raise the temperature to 90° or 95°, closing early in the day.

#### PLANT HOUSES.

*Marantas.*—Repot these plants at once, so as to give them a chance of becoming established before the sun has too much power. They delight in having sweet soil about their roots; and in order to accomplish this, the old soil, or the greater portion of it, must be removed annually, or it is certain to become sour and saturated from the enormous supplies of water the plants require when growing. Turn them out of their pots and work the old soil carefully from amongst the roots, and then place them in clean liberally drained pots. Some care must be taken to dispose the roots as evenly as possible amongst the soil instead of crowding them carelessly. The soil must consist of fibry loam and peat in equal proportions, with lumps of charcoal and a liberal dash of coarse sand freely

intermixed. We have used about one-seventh of decayed manure in the compost advantageously, but prefer feeding the plants after they have filled their pots with roots, for the manure only assists in rendering the soil close and sour more quickly than would otherwise be the case. After potting, plunge the plants in brisk bottom heat until they have commenced rooting and growing freely. The soil used for potting must be warm, and in an intermediate state for moisture, so that water at their roots can be withheld for as long a period as possible. This can be done when the plants are plunged and liberally syringed. If the sun strikes upon them after they have been repotted they are certain to flag, which must not be permitted, for if allowed to flag they are much longer before they become established in the new soil than would otherwise be the case.

*Alocasias.*—These should also be potted, if they are to be in the very best condition, for as long a period as possible. To do these plants really well the whole of the old compost should be removed from their roots annually, for the very best material in one season becomes too much decomposed. Where the root portion of the stem of these plants is too long to allow of them being lowered in the pots in which they are to be placed, a good portion may be removed without injury to the plants. As growth extends they root freely from the collar and upper portion of the stem, and if placed sufficiently low in their pots at the commencement they can be top-dressed with rich material during the growing season.

Alocasias do well in a compost of fibry peat and sphagnum moss in nearly equal proportions, with large lumps of charcoal freely intermixed. The former should predominate, and a good layer of the moss should be placed over the surface after potting has been completed. The pots or pans should be about one-third filled with drainage, and the centre of the plants well elevated above the rim. The material advised for potting should be pressed as firmly as possible into pots as the work proceeds—that is, if the crowns are separated. In many instances this need not be done, as the old material can be washed from amongst the roots without separating the crowns. If possible plunge them in bottom heat to give them a start, and keep them in a close moist atmosphere. The root portions of the stem, if young plants are needed, may be cut up into lengths and laid amongst sandy soil in pans, and placed into the propagating box until they break into growth, when they can be potted singly, or a number placed together in each pot.

*Anthuriums.*—Fine-foliage varieties, such as *A. crystallinum*, *A. splendendum*, *A. Warocqueanum*, and others are most effective plants in the stove when well grown. To keep these in the best of condition they should be repotted annually, and their stems lowered into the pots if they need it. They should not be left unpotted for more than two seasons, for in that time the soil becomes very rotten about the roots, a state of things which should not be allowed to exist. If sphagnum moss is used with the peat, potting should be done annually; if peat fibre with charcoal freely intermixed is used they will do for two years. We use sphagnum moss, peat and charcoal, and repot the plants every year. It is not necessary to give larger pots; on the contrary, if the plants have attained a fair size the same pots may be used for several years in succession. When the plants are turned out as much of the old compost is removed from the roots as possible, and the remainder washed out. The pots are drained, the plants potted and treated afterwards the same as advised for Alocasias. The lower portion of the stem is also removed in the same manner if needed.

Such Anthuriums as *A. ornatum*, very fragrant, *A. Andreanum*, *A. ferriense*, and others are subjected to the same treatment as regards potting at this season of the year. The second named soon grows away from its pots and becomes unsightly if not headed down. This may be successfully accomplished if a good bunch of moss is placed round the stem of the plant just below its main leaves, for in a short time roots will take possession of it, when the head may be severed from the stem and potted separately. The old stem will break freely into growth, which, when large enough, may be taken off and potted singly. These will make good plants in the space of one year. *A. Schertzerianum* should be kept at rest for a few weeks longer in a temperature of 50° to 55°. While in this temperature keep the soil moderately dry.

## THE BEE-KEEPER.

### SUPERING.

THE knowledge of how and when to apply supers is so important to all bee-keepers that it is impossible to dilate too fully upon the means now adopted in this country and America for obtaining the pure white comb honey, which, either in neat sections or other ornamental supers of all sizes, are so commonly seen in shops in our large towns. There has always seemed to be some mystery about this art of supering—for art it most undoubtedly is—which is even now not nearly as generally known as we would expect from the numerous books and leaflets so largely distributed in most of our English counties. That most bee-keepers can obtain some super honey is indisputable, but few are so successful

as to obtain the amount from each stock which may rightly be expected. Either a swarm is thrown and thus the supers emptied, or the queen enters and appropriates to her use for egg laying some of the cells, and so spoils the beauty of the comb and the value of the super as a whole.

It is perhaps useless to attempt to say which kind of super is the one which is most suitable; each one must judge for himself, and as he finds the glass, the divisional, the Stewarton, or the section most readily saleable must adopt that form in all cases when he desires to dispose of his produce. Most probably, however, the 1 lb. section is the most popular super; the size is convenient, neither too large nor yet too small, and the cost of the section itself is nominal.

The hive is to some extent an important factor in obtaining a good yield of super honey; but I am not disposed to lay too great a stress upon any particular form of hive, nor yet to say that either straw, or Stewarton, or bar-frame will in the hands of a competent man far exceed one another in their yield of super honey. All hives, however, should be deep enough to allow some sealed honey to intervene between the brood nest of the hive and comb of the super; the chance of the queen going up into the latter will thus be much smaller than if the brood nest extended to the top of the hive, so that the queen would at times be so near that if cells were prepared and empty, eggs might be laid and the super ruined. It is, however, not of the hive but of the art of supering of which I desire now to write.

In order to obtain supers the stock must be strong in bees and contain a good fertile queen. Now every stock ought to be ready for supering as soon as there is honey in sufficient quantity to fill the supers; every day lost then is a day wasted and profit gone. In most seasons honey may in favourable districts be gathered in quantity from the end of April, and at that time stocks, if properly managed, will be ready for extension. The precise time to place supers must be ascertained by experience; but if the bees are covering all the combs, or if there seems to be a great overcrowding at the entrance, more room is required. Now it is essential to remember that if a super is not placed when required—even a day may make a serious difference—preparations will be made for swarming, and if these preparations are once made it is almost impossible, and it is certainly not wise, to try and prevent the issue of a swarm. How, then, is this difficulty of neither putting on the supers too soon nor delaying too long to be overcome? A beginner may venture to try whether the bees are ready without doing mischief if he will take care not to allow too great an escape of heat from the hive.

If a stock is supposed to be ready for a super let a super be placed on it and warmly covered up about ten o'clock on a fine warm sunny day; if the bees are ready for it they will soon take possession, and all is safe. If, however, in a few hours' time no work has been commenced and no bees are seen in the super the stock may be judged to be unprepared, and a few days may be allowed to elapse, when a second trial must be made; but if the super is not taken possession of in a few hours it should be removed, because any vacant space over the brood nest must of necessity cause the loss of heat and so throw the stock back, thereby causing loss of time. Supers must be wrapped up very warmly; but here again discretion is necessary. After the first glass or box is being worked, if no increase is desired, a second super must be placed under or above the first, when the latter is crowded with bees and comb-building is going on extensively, and so super must be added to super until the close of the season, when no more must be given, but the energy of the bees be the rather directed to the finishing of those already partially filled. Each super, as the comb is filled, must be removed, and so fresh room being given, ventilation being by this means afforded, the desire to increase is prevented, unless owing to the death or disablement of the queen, and super honey in abundance is gained. If sections are used they must be worked in a crate, and if this crate of sections is treated as

one super, and each box is removed as finished, no loss will result, but rather a gain, for each removal of filled sections must, if the piling system is adopted, cause great annoyance to the bees, and loss of time when every hour is precious.

There has been no little discussion as to whether in piling the empty super should be placed above or below the partially filled one. If, however, it is placed below, the first-placed one will generally be first completed, while if the empty one is placed on the top the completion of the first-named one may be delayed to some extent. In hives, however, where there is no breadth of sealed honey between the brood nest and the supers I would allow the first-placed super to remain at the bottom, so acting as a zinc excluder, only much more advantageously, until completed, when it may be removed. It is possible that some of the inner sections may be discoloured, but the beauty of those above will compensate. If, again, this desired breadth of honey is given in the stock I would place the empty super beneath the partially filled one, thus keeping the first-placed one always at the top, until ready for removal.

It is necessary at times to have supers able to contain over 100 lbs. of honey on a stock at once, so heavily do the bees work, and so quickly does comb-building go on at the height of the season. The honey gathered has to lie for a period to evaporate its moisture and ripen before it can be sealed, so that the bees, if stinted of room and finding no employment in the direction of comb-building to engage their attention, turn their thoughts to swarming when their combs are sealed or filled with honey not yet ripe enough for covering. True, bees will swarm at times in the hands of the most careful bee-keeper, but if they do it can generally be traced to some little act of negligence or the presence of a poor queen, either disabled by accident or partially so by age. Sufficient room in advance of the wants of the bees must be given if fine super honey in quantity is desired. Supers must be warmly wrapped up and never interfered with, unless absolutely necessary in order to remove them or to alter something wrong. If not taken possession of they must be removed. Heat must be conserved, stocks kept strong in bees, rich in stores, in roomy hives, well made and admitting of piling. These points being attended to success is assured, and an abundant crop of comb honey, which at present realises the highest prices, will reward the bee-master for his care and judgment.—FELIX.

#### THE PAST HONEY SEASON—THE DARK SIDE OF BEE-KEEPING.

So much has been written in favour of bee-keeping, and such reports of honey and profit (?) obtained, that I am induced to give my experience for the past season as a kind of antidote to some of the assertions made by "A Surreyshire Bee-keeper" and others, that every cottager who can ought to keep bees.

The spring opened cold and dull, feeding light stocks being general till May 26th, when the first honey was gathered here, but barely sufficient to maintain brood-rearing until the Sycamores were all over near my home apiary. Just then a ten-days hot spell came, when bees three or four miles away on the hills, almost on a level with the Heather, and where everything blooms two weeks later, had a fine time of it, first swarms yielding 20 lbs. of surplus honey. This hot weather hurried all up in the valleys; then came a dull time, with a few heavy showers, until haytime. As soon as the weather came fine again the mowing machines were brought out, and in three days' time all the White Clover bloom was cut and drying for hay near home; while on the hills, again, the bees had two weeks' good work before any was cut, when every hive got from 20 to 30 lbs. heavier.

We had no more honey after the middle of July, though we always expect some till the middle of August, no sun, every day being either windy, wet, or cloudy until October. On August 12th I took twenty-seven stocks to the Heather, all very strong, one a 16 lb. lot of driven black bees hived on eight empty combs, with a lot of supers above gathered sufficient to carry them through the winter till April. They worked some of the foundation out in each section (36 lbs.), this lot with

no brood did the best of any; another lot, 12 lbs., did not get 8 lbs. of honey, while a lot of hybrids, with fourteen frames of brood (14 inches and 10 $\frac{3}{8}$  inches), and on twenty-three frames, had no honey when I brought them home, and not a tenth of the bees. I could pick chilled bees up by handfuls from the Heather, having been tempted out by its smell and chilled by the cold winds. I brought all home at the end of September, and as they had neither brood nor honey, I knew from past experience that many of the queens would be encased by strange bees getting into wrong hives, which proved to be the case, as within a week I lost about half of my queens. I got seventeen lots of driven bees and doubled the weak ones, and out of the twenty-seven stocks of August 12th, and the seventeen stocks of driven bees, I made up eighteen stocks for winter, three of which were not good; only one is on natural stores, six are on candy, and the rest sugar syrup.

Thus it will be seen my experience in trying to secure the Heather harvest is an utter failure, as complete as possibly can be, and yet I believe I got more Heather honey than any other bee-keeper in this district. I obtained about 5 lbs. of honey per stock from my home apiary, while on the hills, where all the bloom was two weeks later, the average was over 50 lbs.

So much has been written and said by the squires and parsons about benefiting cottagers by bee-keeping, that I am constrained to just put things together a little. Now, suppose I had been a cottager, and after being at the expense and trouble of taking my bees to the Heather, paying the rent there (1s. per hive is the usual charge), and instead of getting £30 profit, which I expected, having to find £3 for sugar, or lose the lot. How many cottagers, pray, could do it? My observations and knowledge of modern bee-keepers lead me to class them as gamblers, always expecting better luck, and every good haul being a bait to get further in the mire. It will be a sorry day for this country when bee-keeping is taught to every village boy as "A. S. B. K." wishes.

Cottage bee-keeping was perfected ages ago, hundreds of years before the *British Bee Journal* was published. Is there a modern frame hive which displays such profound thought to conceive it as the despised skep? or to compare with it in cheapness? And how simple the management!—viz., hiving swarms and brimstoning those not wanted for stocks. No slow feeding brood spreading, manipulating, removing old queens, or the thousand odd jobs necessary in a modern apiary; all using up valuable time, never to be debited against the profits. Oh, n the bees work for nothing and keep themselves. These are they who make all the large profits, and goes red hot to drive his poor barbarian neighbour's bees to save them from a cruel death, but for all his talk cannot persuade him to alter his ways and never will.

I have nothing to say against modern bee-keeping as a hobby. This is all it is fit for at present, probably in a while it may be made to pay when plenty of capital can be employed with a good reserve fund against bad times, also a reliable table established of the average losses from various causes and average yields of honey one year with another, and above all something definite about the laws that cause a good season to follow a disastrous one. Then we may have bee-keeping followed as a business and honey selling at 6d. per lb. In fact, let modern bee-keeping be scientific in fact as well as name.—A HALLAMSHIRE BEE-KEEPER.

#### TRADE CATALOGUE RECEIVED.

Vilmorin, Andrieux, & Cie, 4, Quai de la Mégisserie, Paris.—*General Catalogue of Seeds for the Spring, 1886.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relat-

ing to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Erratum.**—In the notes on "A useful manure," p. 84, last issue, reference to the soil for Primulas, should read "one barrowload of night soil, three of loam," &c. By a printer's error light soil was substituted for the above.

**Books on Moths (A Subscriber).**—There is really no good and comprehensive book upon our British moths. The best extant is Newman's "Moths" (Bogue) reduced to 16s. we think, but this does not take the smaller species. Stainton's "Manual of Butterflies and Moths" (Van Voorst) about 7s., has all, but this may be out of print. Morris's "Natural History of British Moths" in four vols. is costly (£4 4s.), and you would perhaps not think it worth the price.

**Bulbous Plant (F. G.).**—We do not know the plant by the name you give, and we cannot recognise it by the description that the bulb is "18 inches in circumference." You also do not state whence it was obtained.

**Gooseberry Branches Dying (Somerset).**—We have received the box, the contents of which shall be examined and an answer given in an early issue.

**Back Numbers (J. S. U.).**—It is quite impossible for us to say whether there are purchasers for the particular numbers you have or not, and consequently whether it would be of any use to advertise them. Why not bind them? They would be valuable to you for reference.

**Scale on Conifer (T. S.).**—Your specimen, which appears to be *Thujopsis borealis*, is infested with scale. Syringe it well with a solution of softsoap, 2ozs. of soap to each gallon of water, adding to that quantity a small vine-glassful of petroleum, agitating violently and keeping briskly stirred all the time the syringing is being done. Do not apply it at a time when the sun will shine on the tree while it is wet with the solution, or the dressing may be injurious; otherwise it is quite safe and effectual in destroying all the scale it reaches.

**Heat of Mushroom Bed (G. H.).**—If the temperature on the soil under the covering can be kept about 50° it will be quite right, a few degrees above or below not being material. As it has fallen to 46° double the thickness of covering. Many beds are now covered to a depth of 2 feet or more with litter, the state of the weather and the condition of the beds alone guiding in this matter. We do not apprehend failure in your case if you act as suggested.

**Primula (G. A.).**—While we are not prepared to say that your Primula is distinct from all others, it is deeper in the purple than most, also very good in form and substance and worthy of preservation. There is, as you know, a slight variability in the colour of Primulas, even on the same truss, and an individual flower is not sufficient for the purpose of forming a definite and decided opinion as to its absolute distinctness and superiority over other varieties closely resembling it.

**Abnormal Primula (H. J. Stokes).**—This flower represents a freak of Nature, the calyx being transformed into a leaf after the manner of the Jack-in-the-Green in hardy Primroses. We have seen many similar examples, but not often with the peculiarity so fully developed. It appears to be to some extent hereditary, but we cannot regard it as a "new strain," nor "good for exhibition." A double Primula of the same character would be suitable for coat decoration, but single flowers soon wither.

**Peaches under Glass (B. R.).**—We have no work on the cultivation of the Peach under glass, and you will not find any better information on the subject of your inquiry than is contained in a year's numbers of the Journal, under the heading of "Work for the Week."

**Custard Apple (Journeyman).**—The Custard Apples are produced by species of Anona. The common Custard Apple is *A. reticulata*; the Sour Sop is *A. muricata*, and the Sweet Sop is *A. squamosa*. They are all natives of tropical regions, either the East or West Indies, and therefore require a stove temperature when cultivated in this country. Give the plants a light compost of two parts loam to one of leaf soil, and encourage growth as much as possible, afterwards well ripening this by exposure to the sun. It will, however, take several years for the plants to reach flowering size, and even then it is doubtful if you will succeed in setting the fruits.

**Mushroom Failing (Discouraged).**—The firm you mention are not growers of Mushrooms, but vendors of very good spawn. The process described in the work you mention is founded on successful experience, and is perfectly correct. Some manure will not grow Mushrooms, especially where horses that produce it are systematically under treatment with medicine. Some persons also fail with the best of manure, while others succeed. It is the same in most other pursuits. We have a letter before us in which the writer says he has "just gathered a peck of Mushrooms from one end of an outdoor bed." He carries out the method advised. Cover the bed very thickly with litter, and on the return of milder weather it may probably become warm enough for spawning. It is of no use inserting spawn at present. Beginners should always take care to commence at the most favourable time, and this you have perhaps overlooked. Either the manure is faulty or you have erred in management, for it is certain the instructions are sound.

**Notice to Leave (A.).**—In the absence of any written agreement to the contrary the term of notice to leave is usually determined by the periodical payment of wages. If you are only paid half-yearly you are not, in our opinion, paid often enough. If you give your master a written notice the day before your wages are due that you intend leaving on the expiration of the next term he is bound to accept it, or at least you can leave when the time comes if you can adduce satisfactory evidence that the notice was placed in his hands. If you want to leave on shorter notice you had better act on the advice of a solicitor.

**Vines Unsatisfactory (One in Trouble).**—The Vines are probably weak and the wood not matured, and hence the buds not prominent and well supported. You have also commenced forcing too early, considering that the

roots of the Vines are in a cold outside border. You have, in fact, attempted what is practically impossible under the circumstances, and considering the state of the Vines. All you can do now is to encourage them to make good foliage, and wood to be well matured for another year; then if you must commence forcing so early cover the border with fermenting materials. You might do so now with advantage to the growth.

**Propagating Ficus elastica (H. H.).**—If the side shoots that are a foot long are getting a little firm at the base they will strike if firmly inserted in small pots of very sandy soil surfaced with pure sand kept moist, and the pots plunged in a bottom heat of 80° to 85°, in a case or under a handlight, to arrest the evaporation of the moisture from the leaves. Perhaps the best plants are raised from eyes or portions of ripened wood containing them, inserted much the same as Vine eyes, but each with a leaf attached, coiled round and supported by a stake, and kept fresh till roots are emitted and fresh growth starts from its base. The process is described by "J. H. E." on page 94 last week.

**Improving Lawn Tennis Ground (F. A.).**—Give a surface dressing of rich compost, such as thoroughly decayed leaf soil or the refuse from the garden, and all the better if charred or thoroughly decayed manure, early in April. Rake it in well, and with an early prospect of rain sow 12 lbs. finest lawn mixture, which may be obtained of any respectable seedsman, you stating what you require it for, and asking to have Clovers omitted, as these keep the ground too long damp in the morning. If you choose to sow your own mixture procure 8 lbs. *Cynosurus cristatus*, 2 lbs. *Festuca duriuscula*, 1 lb. *Festuca tenuifolia*, and 1 lb. *Poa nemoralis sempervirens*. Rake lightly after sowing, and roll the surface, not mowing the grass for a fortnight, and then keep the lawn well rolled.

**Vine Shoots Eaten (F. G.).**—The examples sent look very much as if they had been attacked by the Vine beetle. You had better make a careful search with the aid of a lamp or candle at night, and you may possibly find the enemy. The beetles are not, however, very easily seen, and a very careful examination of every point of the Vine should be made. You had better perhaps tie some cotton wool round the stems and smear it with petroleum.

**Mushrooms not Growing (Grower).**—There is nothing wrong with the beds, the Mushrooms do not grow simply because the temperature is too low, the weather lately having been severe. A thicker covering would not have done any harm, but have made the temperature more suitable for and accelerated the growth of the Mushrooms. With warmer weather you will no doubt have an abundant crop, as the beds seem in capital condition. The instructions in "Mushrooms for the Million" are sound, but all those for outdoors and in cool places are contingent of the weather, as a temperature of 50° is essential for the development of Mushrooms, and that can hardly be secured even with a good thickness of covering material in an out-house this winter. We have had many beds similarly located that with a thicker covering or 6 inches have given Mushrooms even in frosty weather, and with milder weather an abundance, the covering then being reduced to a couple of inches, so as to insure uniformity of moisture and temperature. As the weather becomes warmer give tepid water if the soil be dry, keeping the water from the clusters—i.e., avoid watering directly over them, and allow it to soak in before again covering the bed. Write to the Secretary of the Society about the medal.

**Vine Roots in Outside Border (Merchant).**—Yours is not by any means an unusual case, the roots being often more abundant in the outside than in the inside border. This generally arises through the more uniform moisture outside. We should not at present interfere with the roots in the outside border, but it would be advisable to re-make the inside border and relay the roots found there nearer to the surface, and by keeping the border moist and mulching you will be able to fill it with roots, and then you may operate on the outside border in a similar manner. We should not lift the roots from the outside and bring them inside, as that would give a check, in all probability be fatal to the crop. There is no harm in the roots going outside, and we certainly should not seek to confine them to the inside by bricking up the arches by which they pass from the inside to the outside border. We should cut out the Vines of Muscat Hamburgh, and either plant young Vines or train canes from the others in their place.

**Auriculas not Growing (J. L.).**—There is certainly something in either the soil or the sand that is injurious to your plants. We should obtain both loam and sand from a fresh source, shake out the plants, wash the roots, and place them in small well-drained pots, using some wood ashes or crushed charcoal plentifully with the compost. If you can scrape some dryish leaf soil from the surface of the ground in a plantation or wood, not of Fir trees, this would be excellent for mixing freely with the loam and sand for inciting the production of roots, and far better than leaf mould that has been found in heaps after fermentation. You must apply water with great care, and protect the plants from frost. There may be iron in the soil for anything you think to the contrary. At any rate, use no more of it, but get what you can in the manner suggested—loam as well as leaf mould if you can collect it from under Beech or Oak trees. Half the bulk of the compost may be of the natural decayed leaves until the plants have produced fresh roots, then repotting in a preparation in which loam predominates. Let the pots be quite small, and if you plunge them in ashes the soil will be kept more uniformly moist without giving water frequently. We regret your failure, and trust we have pointed out a remedy.

**Eucalyptus in a Hall (Mrs. H.).**—You say the tree has been "lately removed into a tub." If by lately you mean since October, the check to the roots is quite sufficient to account for the collapse of some of the leaves. Further, you say it has had "exactly the same treatment" as to watering in the hall as it had in the greenhouse. It would require different treatment—that is, not nearly so much water, after being removed and placed in fresh soil as before. If the old soil—that in the pot—happened to be dry in the centre of the mass when the tree was shifted, and the new soil has been kept quite wet, that would be quite sufficient to account for the condition of the leaves. If you had asked us about removing it from the tub after September we should have advised you to wait till March or April. The dry air of the hall has been the reverse of favourable, but we attribute the chief mistake to injudicious watering after the tree was placed in the tub. Nothing you can do will cause fresh leaves to form on the stem, and all you can do to

prevent the trees getting worse is to give sufficient tepid water to penetrate the entire mass of soil whenever the earth shows a disposition to crumble when rubbed, and never until then. It will not injure the tree to nip off the leader in March. This, provided the root-action is healthy, would result in an increase in the number of growths near the top, not at the base of the tree from whence the leaves have fallen. Those above, between the tiers of branches, will fall also if good judgment is not exercised in watering. You had better, perhaps, get a young tree and grow it in your greenhouse to take the place of the present one if it should not recover.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear sp. es. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (J. A. P.).—*Cypripedium carolinum*.

### PROFITABLE FARMING.

THAT thrift and industry are thoroughly exemplified in small Sussex farms is undoubtedly true, as it is equally true that by the exercise of self-denial and by almost incessant

labour none of the farmers have had to give up farming or failed to meet their engagements. To obtain more land, larger farms, is the common aim of such men, and, laudable as this may appear, it is frequently the rock on which the hopes and efforts of years are shipwrecked. We are intimately acquainted with more than one instance of this. In one case the farmer had managed his little farm of thirty acres so well that he had brought up a large family, had saved enough money not only to enable him to purchase a cottage or two, but to render him dissatisfied with his profitable little farm, so that at last he left it for another of a hundred acres. From that time he ceased to be a prosperous man, and he entered upon an incessant struggle with difficulties, the primary cause of which was insufficient capital for such an undertaking. Ten pounds an acre has repeatedly been quoted as the amount which a farmer requires at the outset, but in many an instance he would do better, much better, with £15, or even £20 an acre. Let it not be thought that the investment of so large an amount per acre points to extravagant or reckless expenditure, but rather to the laying out of capital in such a manner as shall afford a large, speedy, and profitable return. This is one of the useful lessons so strongly enforced in the reports of the farm prize competition by the Royal Agricultural Society, and we strongly commend it to the attention of our readers.

Depend upon it, high farming still answers better than any other, only there must be keen intelligence, sound sense, and energetic action brought to bear upon it, and, we may usefully add, rigid economy. Granted reforms in agreements, in preferential rates, in local and imperial taxation, and in rents, to ease the burdens of the land, we are bound to insist that the farmer on his part strives earnestly for increased knowledge, better work, careful management, closer attention to details, a fuller development of what have been termed minor profits. The time for hard-and-fast rules of practice has long been past; we are all the sport of circumstances, and our farm management to be successful must accord with situation, seasons, and markets. Every year brings its peculiar trials and lessons, and we may add its opportunities. When the drought of last summer forced many a farmer to send his starveling ewes into the market in such large numbers that every pen was crowded to overflowing week after week, and prices fell to abnormally low rates, there was an opportunity for the realisation of "minor" profits for those who were in a position to turn it to account. This was a matter peculiar to the season and markets, worthy of especial remark, as denoting losses on the one hand and profits on the other.

Peculiarities of situation must always exercise a special influence upon the farmer's work. We showed last week how well the Sussex farmers turn the peculiar advantages of that favoured county to account. The report of the farm prize competition of last year affords valuable information of some clever and profitable practice in the north. Take for example Mr. Ashton's first-prize farm of 166 acres near Liverpool. Hired from year to year, without restrictions as to cropping or sale of produce at the high rent and tithe charge of £391, it is farmed under a system altogether adapted to the situation, everything which the farm produces being sold at Liverpool, the vehicles loading back with manure, principally from stables using sawdust bedding, but also from cattle sheds and latrines; the only exceptions to the carrying out of this system to the letter being in the case of autumn aftermath, which is let to cattle salesmen for grazing purposes, and realises about £60 a year, and also the produce of six acres of permanent pasture used for the grazing of stock. Mention is made in the full report of this farm of a working capital of £2000, of a labour bill of £600 a year, and of an annual manure bill of nearly £400. The cropping for last year was 34 acres winter Wheat (19 acres after lea, 15 acres after Potatoes and Turnips); 17 acres of Oats (5 after roots, and 12 after lea); 15 acres of Barley (5 acres of Tares, 22 acres of Potatoes, 2 acres of Swedes,

1 acre of Mangolds); 42 acres of first year's seeds (22 after Oats, and 14 after Wheat); 22 acres of second year's seeds (6 acres of permanent pasture). No strict rotation is followed but it is usually—First year:—Fallow crop, mostly Potatoes, and a few Swedes and Mangolds. Second year:—Wheat sown down with seeds. Third and fourth year:—Grass, usually cut five times in the two years. Fifth year:—Oats, and sometimes Wheat. The judges stated that—"If the total produce of crops were added together, and valued even at current market prices, low as they are, there would be no difficulty in proving that Mr. Ashton's general management with a view to profit is on a sound basis, and fully meets the requirements of the Royal Agricultural Society." Mr. Ashton's mixture of Grass seeds for his two-year layers is half bushel Pacey's Perennial Rye Grass, half bushel Italian Rye Grass, 3 lbs. each of Red Clover, Cow Grass, and Alsike Clover, 2 lbs. each of Timothy, Cocksfoot, Crested Dogstail, and Rib Grass, 1½ lb. each of Trefoil and Giant White Clover, and 1 lb. Sweet Vernal.

(To be continued.)

#### WORK ON THE HOME FARM.

Arrangements now being made for the application of what are usually termed spring dressings of manure are important, and demand our close attention, for upon the correct and timely doing of this work depends the degree of success to be achieved this year. Two things are all-important here: sow the manure early, and see that it is genuine. Avoid dealers' mixtures; procure each sort of manure separately, and have the mixture made under careful supervision at the farm. All winter corn must be dressed during the present month, to wait till March is to court failure. Do not forget that artificial manure must be dissolved by rain before it can be absorbed into the soil as food for plants. Apply the dressing to spring corn at the sowing, the manure to be sown broadcast immediately after the drills and before the harrows are used, in order that it may be so mixed with the surface soil that it may be held there, and some of it dissolved even before rain falls. Drought not unfrequently sets in early in March, and remember we do not always get April showers, and therefore in common prudence we must sow the manure so early as to insure its absorption before vigorous growth begins. For grass land early sowing is, if possible, even more important, and with timely sowing the effect of the manures we have so often recommended is more speedy and equally beneficial to that of farmyard manure, while it is much more economical. The manufacture and application of farmyard manure to pasture is so costly that one cannot but feel surprised it has gone on so long. To the mind of the ordinary farmer there is virtue in bulk and rank odours, and his perception of the real value of artificial manures is still vague and undefined. One has still to offer a sort of apology for making mention of them to him. The best way to attract his attention and to induce action for his own benefit is to give him tangible proof of the effect of artificial manure in the guise of superior crops. There must be no fitful hap-hazard use of these manures, but a certain quantity must be applied every year, so as to keep the land stored with fertility. We append the formula for Grass crop:—Half cwt. nitrate of potash, three-quarter cwt. nitrate of soda, half cwt. superphosphate, half cwt. steamed bone flour. Spring dressing for corn crops:—Quarter cwt. nitrate of potash, three-quarter cwt. nitrate of soda, quarter cwt. steamed bone flour, quarter cwt. superphosphate, quarter cwt. coprolite. For root crops:—Three-quarter cwt. nitrate of potash, half cwt. nitrate of soda, 2½ cwt. steamed bone flour, 2½ cwt. ground coprolite. Each formula is for the quantity required per acre.

#### REMARKS.

31st.—Continuously wet early and heavy rain at intervals till 1 P.M.; bright afternoon; clear night.  
1st.—Fine bright day.  
2nd.—Fine and bright.  
3rd.—Snow in early morning and till 10.30 A.M.; dull, damp, and slightly foggy after.  
4th.—Fine and, as a whole, bright; but a few spots of rain about 1 P.M.  
5th.—Fine, but without bright sunshine; fog about sunset.  
6th.—Beautifully fine and bright, but colder.  
On the whole a fine week. Temperature almost identical with that of the previous week, and rather below the average.—G. J. SYMONS.

### THE ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW AT LIVERPOOL.

ORTICULTURISTS will welcome the announcement that the necessary preliminary arrangements have been made and the date fixed for a provincial Show at Liverpool in the present year. It was stated in the annual report that an invitation had been received from the Mayor and Corporation of that city, and that substantial guarantees were offered to induce the Society to hold an exhibition there. The pro-

position was so favourably received that the Council appointed a deputation to consult with the Mayor of Liverpool, inspect the proposed site, and make such other arrangements as they might think needful. On Saturday last the deputation was most cordially received by the Mayor and other officers, the matter was fully discussed, and in the result the Botanic Gardens and Wavertree Park were placed at the disposal of the Royal Horticultural Society for the purpose of the exhibition, the entire management being left in their hands and those of Mr. Richardson, the excellent Curator of the Gardens. The Council was further assured of the hearty co-operation of the Liverpool officials and horticulturists, and the formation of an ample guarantee fund was undertaken.

The date received careful consideration, but it was finally determined that the exhibition should open on Tuesday, June 29th, and remain open six days, closing on the following Monday. This is somewhat earlier than had been originally intended, but it was found to be more convenient in many respects, and will only necessitate great promptitude in the preparation and issue of the schedules. The success of the Show from a horticultural point of view will no doubt depend to a great extent upon this, and no time should be lost in placing these before intending exhibitors. The prizes also must not be stinted, and if the arrangements throughout are made in a liberal spirit it is confidently anticipated that the Society will score one of its greatest successes, provided only that all-important factor the weather be favourable.

The site chosen is a very convenient one, easily accessible by tramcars and other conveyances, and it adjoins the great Shipping Exhibition, which will attract so many thousands of visitors to our great northern seaport this year. There is also a strong horticultural enthusiasm in the neighbourhood of Liverpool, as is proved by the excellent annual shows there held, which are rivalled only by those at Manchester. With strong local support and the friendly aid of horticulturists in other parts of the Kingdom an exhibition of remarkable beauty may be easily provided, such as will conclusively indicate that the revival of the Royal Horticultural Society's provincial shows is in every respect desirable. With the experience of the past to guide them, and having regard to the continuous influx of visitors to the "Ship-eries," also weather contingencies, the Council did not feel justified in making the requisite provisions which must necessarily be of great magnitude for a shorter term than

six days; and this being so, the dates of opening and closing were rendered necessary in consequence of the National Rose Society's Show at South Kensington, that has been fixed for the day after the closing of the "Provincial," from which the staff of the Royal Horticultural Society must be liberated.

### IMPORTED ORCHIDS—MADE-UP SPECIMENS.

MADE-UP specimen Orchids have caused much dissatisfaction for purposes of exhibition, and have occasionally been strongly commented upon. There is every reason to hope, however, that the practice of packing a number of small plants together in a large pot or pan will in a few years become obsolete. In these days of quick travelling large masses are imported in perfectly fresh condition, and in about two years with good cultivation they will produce strong-flowering pseudo-bulbs. The time required to thoroughly establish the plants entirely depends upon the treatment they receive, and the freshness of the plants when they arrive; but these large masses are now landed almost as perfect as when torn from the trees in their native habitat. It will be remembered that a sensation was created when an enormous *Cattleya* was conveyed safely to St. Albans, but since then large specimens have been the rule rather than the exception. Recently I had the pleasure of inspecting some plants of *Laelia anceps* and *L. albida* fully 3 feet in diameter and nearly as much in height, with plump pseudo-bulbs and with green fresh foliage. With good treatment such plants would make flowering pseudo-bulbs in one season and as strong as the original ones the second. When such plants as these can be imported in good condition there will be no need for making up specimens.

When these large plants are established in pots or pans, on rafts or blocks, those who have not seen such specimens at the time they were removed from the travelling cases may still be inclined to think that they have been made up, the more so because it is almost impossible to secure them in position in the exact manner in which they arrive. This cannot be done, neither is it advisable to try to do so, for in many instances if the plants are to be rendered really presentable they must be partly separated. This is not necessary in all cases, but where the leading growths are not regularly and evenly disposed they must be arranged at suitable distances over the pan or raft, so that when they flower there will be a regular head of bloom. Of course, it will always be very difficult to prove that they have not been made up, but this in every case cannot be helped, while in others leading growths may be bent and pegged into the position they are wanted without severing them from the remainder of the plant. It is often wise to remove a large number of old pseudo-bulbs as soon as the plants are received and before any attempt is made to start them into growth. It must not be inferred from this that I advise the removal of any that are perfectly fresh and plump, or any that will become so when heat and moisture are applied. This must not be done, for strong breaks often start away from these fresh plump leafless pseudo-bulbs. This is especially noticeable in the case of *Laelias*, *Cattleyas*, and many others; in fact, we have often had as strong growths from these as the leading ones.

Those who have only seen or purchased moderately small plants, after they have been cleaned, have no idea of the number of pseudo-bulbs in various stages of decay that exist about large masses. In a state of nature the decaying pseudo-bulbs cannot be removed, but decay or are dried, until they have the appearance of a quantity of peat amongst the stems and roots. These should be removed before the plants are subjected to heat and moisture. Those experienced in cleaning and trimming imported Orchids know exactly what to remove and what to leave. Those whose

experience is limited should remove all decaying portions and others directly they show signs of decay when placed in heat.

When Orchids are first imported light, heat, and moisture must be gradually admitted. The effect of strong light on the plants may easily be imagined after they have travelled a long journey confined in a dry case, for in this way only are they certain to arrive in good condition. Strong light combined with heat and moisture causes the plants to decay. Moisture should be most sparingly applied at first; in fact, any plant house if kept moderately dry will be suitable at first without syringing. If subjected only to a moderate temperature with proportionate moisture in the atmosphere they become plump and start strongly into growth in due time. More imported plants are injured by the application of strong heat from the first than by any other cause. If they are forced into growth they are generally weak, and the plants are a long time before they produce pseudo-bulbs strong enough to flower. The secret of success in establishing imported Orchids is to start them gently as regards heat, and when they are progressing to help them in every possible way to make a sturdy compact growth. If the Orchids are in good condition when they arrive, and are well treated, then they will make strong growth the first season, which must be ripened, and the plants will advance the following season with increased strength.—S.

#### POTATO PLANTING.

THE Potato is perhaps the easiest vegetable to grow to secure some sort of a crop, but to obtain fine and plentiful produce requires thought, observation, and care. The different varieties of Potatoes require very diverse treatment, and it is chiefly owing to the rough and ready way of treating all alike that many growers differ in their estimates of varieties. It is unwise to judge a Potato from one season's results, for with some varieties that have disappointed me the first season I have first-rate results the following year. For instance, a few years ago I paid a high price for a pound of a new variety, and took great care in the planting, giving them my best ground, only to obtain a small crop of anything but fine tubers. I hastily resolved that the variety was worthless, and the following year after planting the others I roughly put these despised ones into a poor piece of ground in a corner and never troubled more until lifting time came, when I was surprised to find a fine crop of handsome Potatoes.

I prefer a whole set to a cut one, and as a rule I prefer rather large ones—the size of an egg; but here discrimination is required. Of weak growers I select large seed, and of such strong ones as Magnum Bonum tubers half the size of an egg are large enough. If required for exhibition one strong eye is quite sufficient to leave, and for a crop three, cutting the remaining eyes out. I usually slice a small piece off the heel also. A friend of mine cuts all the crowns off his tubers, leaving the side eyes only, but I cannot recommend this practice, for I have tried it with anything but satisfactory results.

In planting, if the soil is light I consider 6 inches the proper depth, but if heavy it is far better to draw a shallow drill to place the tubers in, drawing the soil from the sides to cover them. This will in wet weather keep the Potatoes high and dry and less liable to disease. When moulding up the season must be taken into consideration, for if very dry and hot, or promising to be so, it is best to draw up as much soil as possible, and if showery a slight moulding is quite sufficient.

If time and trouble can be afforded it is well to draw narrow trenches about 9 inches wide and 6 deep, placing the seed from 15 to 18 inches apart, and a yard from row to row, then cover them with good leaf mould mixed with old mortar rubbish well pulverised, and a heavy dressing of the Aylesbury Native Guano, than which I know no better manure for Potatoes. I have tried it two seasons with most excellent results. It is more profitable to give Potatoes a yard from row to row, or even 4 feet to strong growers, than to crowd them in at 2 feet apart. They obtain plenty of sun to all the foliage and a good circulation of air just when they are growing well, and require these aids to fruitfulness, and a good crop of Broccoli, &c., can be obtained by putting out plants between the rows, thus leaving no ground unoccupied.

Of varieties Sharpe's Victor and Veitch's Ashleaf are admirable for earliest crops, and the former is very useful in frames. To follow these Sharpe's Duke of Albany and Match-

less come in as second earlies, whilst for later crops I can very strongly recommend Sutton's Reading Russet, Vicar of Laleham, and Snowdrop. All the above varieties are of high quality, good croppers, and in addition are all excellent for exhibition. I have grown over one hundred varieties, and I cannot surpass this selection, but if more are wanted for exhibition alone Porter's Excelsior, International, and Feltham White are excellent for this purpose.—H. S. EASTY.

#### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 84.)

##### SOILS FOR FINAL POTTING.

MUCH depends upon the soil used for potting Chrysanthemums to obtain successful results. More particularly does this apply to the final potting. Soils of a complex nature are often recommended, as if elaborate mixtures necessarily possess extraordinary virtues. Good soil is important, but at the same time is only one element in the case. Growers who depend almost solely on fanciful mixtures for the production of flowers of the finest quality have much to learn. The effects of the best compost that can possibly be obtained may be completely nullified by errors in watering and general management. Without using soil of a proper character success cannot follow, but the after treatment of the plants is the all-important part to be studied. As Chrysanthemums have such a short season of growth, and so much has to be done in a few months, they must have all the support they can appropriate, and to this end the composition of the soil is not of so much importance as after-feeding. The soil, then, while it contains food must be regarded as a store for additional food that is required and given from time to time, the store or larder all the time remaining sweet. It is a mistake to suppose that soil must be prepared and stacked for six or twelve months previous to using it, and I am glad to see that old practice is fast becoming obsolete. Soils differ so much in their nature and component parts in different parts of the country that no absolute rule can be laid down as to what mixture is the best. I will endeavour to make this part as clear as I can to suit the various localities, first describing the different ingredients used.

Loam, as it is called, is composed of the top spit of an old pasture, cut in thickness according to the depth of the fibrous roots of the grass; in some places 3 inches is not too deep, while in others 1½ inch is enough according to the time the pasture has been laid down. It should be cut about three months previously to being used, or just long enough for the grass to decay, and prevent it growing through the surface in the pots. If the turf is light in character, and cut from where the land is of a sandy nature, ground oyster shells should be added, which have a portion of lime in them; but if the turf is taken from a district where chalk and limestone abounds add more charcoal and wood ashes in lieu of oyster shells. Charcoal is of great assistance in keeping the whole soil porous and acting as a storehouse for ammonia. If the turf is of a retentive character remove the fine soil by means of sifting through a fine sieve, as this fine soil tends to prevent a quick passage of the water when applied copiously, as it must be during hot weather in summer. Those growers having a rather light soil at disposal are much more favoured than those with soil approaching clay, as where the former kind is used the moisture escapes from it quickly, consequently feeding can be more frequently and safely carried out; therefore due care should be given to making heavy soil lighter.

Manure is the ingredient second in importance, and must be applied in some form or other. Well-decomposed cow manure is often recommended, such as falls to a powder when moved. This is wrong, because what beneficial properties can there possibly be in manure when decomposition has entirely taken place? Simply the shell is left which held the goodness; and it is the same with decomposed hotbed manure, as the violent heat caused by the mass during fermentation dissipated the ammonia, and it is the ammonia which should be preserved for the benefit of the plants. I do not approve of cow manure in any shape. I consider it injurious when used with soil of a heavy character, it being too close in nature, and far too binding with other parts. The best manure is that prepared as if for a Mushroom bed, excepting that the straw should be taken out. It is sweetened, yet most of the ammonia is retained. This is the best manure to employ for soils of both a light and heavy character. Fine ground bones, as well as dissolved bones, are also beneficial when used in proper quantities. Soot is a powerful and a beneficial agent when cautiously applied, but when used excessively it is most injurious. I have seen plants which had lost all their leaves and others presenting a very sickly appearance through the misuse of soot. Lime in a quick state is useful for the destruction of worms, the quantity used being in accordance with

the district from where the turf was obtained. In mixing the soil a handful sprinkled on occasionally is all that is required for the purpose. The sand used should be coarse and gritty, that which is fine and liable to bind together the other materials should be avoided. Clean coarse silver sand is the best. Leaf mould in a half-decayed state is an excellent ingredient to add, particularly in the case of heavy retentive soils, as it is of great assistance in keeping the whole mass porous.

Having described the materials to be used, let it be understood, for the final potting, as in a previous note I indicated the soil best adapted for them in the younger stages of growth, I will now give as near as I can the quantity of each component part. To be precise I purpose taking the two cases in hand—heavy and light soils, and give the details required in each composition. Taking the former kind first, I would advise as follows:—Three parts of fibry loam broken up roughly, the fine soil taken out, retaining nothing but the fibrous parts, one part of horse manure, one of half-decayed leaves, one part of coarse silver sand, a quarter of a part of fine ground bones, and the same quantity of dissolved bones; one part of charcoal and wood ashes, the former to be used in a rough state, adding a 6-inch potful of soot to 4 bushels of soil.

Where the loam is light in texture use four parts as fibry as possible; to this add two parts of horse manure, one part of leaves, half a part of coarse silver sand, the same quantity of ground oyster shells, half a part each of fine crushed and dissolved bones, and the same quantity of soot as advised for the heavier soil, thoroughly incorporate all the parts together, using all that can be so used in a rough state, as the action of mixing reduces the parts considerably, therefore if the turfy loam and other ingredients be chopped small at first, the mass becomes too fine through frequent turnings. The compost should neither be too wet nor too dry, but just a "happy medium," for if wet it is liable to run together too closely, and if it is too dry it cannot be made sufficiently firm in the pots.

#### RIGHT AND WRONG METHODS OF POTTING.

Chrysanthemums must be potted in a proper manner, or it is useless to expect flowers of the finest quality, therefore this part of their culture should be carefully considered. To the inexperienced growers potting Chrysanthemums may appear of no greater importance than potting any ordinary softwooded plant; but high-class blooms cannot be had from plants with soft sappy stems, which are the results often of improperly performing this part of their treatment. When they are potted loosely they grow strongly and produce large leaves, but are devoid of that solidity which is essential to success. The soil should be rammed into the pot very firmly with a blunt stick 1 foot long and 1½ inch in diameter at one end, the other end being cut wedge-shaped. In soil of a light character it is hardly possible to pot too firmly, but it is not so necessary with heavier soil, as the water will not percolate so freely, and should the drainage become defective trouble may ensue through the soil becoming waterlogged. When the plants are potted firmly the growth is not so rapid early in the season, but it is rendered solid and firm as growth proceeds, and is more likely to mature in a wet autumn. Let it be understood that I am now referring to the final potting.

As I stated before, the pots should be perfectly clean; the crocks used for the drainage also must be free from grit. For the largest pots 2 inches of drainage is not too much, and it should be carefully laid in. The piece placed over the hole in the pot should be much larger than the hole and quite hollow, not flat and close-fitting. Other pieces coming next should be smaller and properly packed around the first piece, finishing off with a layer of smaller pieces. Over the drainage place a layer of the roughest parts of the compost to prevent the fine soil running down amongst the drainage, thus preventing the free egress of water. The best material for this purpose is pieces of thin newly cut turf, as this does not decay so soon and is not so liable to clog the drainage. In the case of the heavy soil sprinkle a few leaves, charcoal, and a table-spoonful of soot over the pieces of turf. If the soil is light the soot only will be required. The soil should be firmly rammed down previous to placing the plant thereon. Do not cover the top of the ball of soil attached to the plant too deeply. Give a little to cover any surface roots that may have become bare through watering, but leave a depth of about 1½ inch to allow space for water and top dressing at a future opportunity. If the soil is moist no water will be required for two or three days; after this time a good soaking may be given.—E. MOLYNEUX.

(To be continued.)

#### GOOSEBERRY AND CURRANT CUTTINGS.

THERE are no fruit-bearing bushes or trees easier propagated than Gooseberries and Currants. Anyone who possesses the cuttings and a piece of garden may accomplish it. Cuttings should only be taken from

the best varieties, and the time to select them is at the pruning. Strong young shoots from 10 inches to 1 foot in length make the best cuttings. They should be well developed and thoroughly matured; cut them square, or nearly so, at the bottom, and the top should also be taken off with the knife, as the terminal bud is not a good one to form a handsome bushy top. When it is desired that the bushes should have extra long stems, long cuttings must be used. For ordinary dwarf bushes cuttings with 9 inches of a stem and 3 inches of a head will be found to answer well. In this case the whole of the buds, from the bottom upwards for 9 inches, must be nipped clean out, and as 3 inches of this will be required to be inserted in the soil, each bush will have a clear stem of 6 inches. Taller plants may be produced by making the cuttings 16 or 18 inches long, and then 3 inches of entire buds at the top will be sufficient to leave to form a handsome head. We are in favour of bush fruits having long stems, as when the branches grow out and incline downwards the fruit is sure to be bespattered with mud during wet weather, and we have known large quantities ruined in this way. This is the result of having the stems too short.

Many who have been looking forward to increasing their stock this spring would select their cuttings when the bushes were pruned, and since then they will have been resting with their ends in the soil, but it is not safe to leave them longer in this way, as a little mild weather would soon induce the buds to swell. They should be placed in rows, allowing 15 or 18 inches from row to row, and 6 inches between the plants. We have begun digging at one end of the piece they were being put into, and each row was placed in as the right distance was reached; but we never do this now, and prefer digging the piece first and dibble the cuttings in afterwards. They ought at least to be let 3 inches into the soil, and they should be made firm by treading round each one with the feet. They root quickest in a light sandy soil, and although a few may fail to grow, the majority will become good bushes.—A KITCHEN GARDENER.

#### CULTURE OF PEAS.

In my notes upon this subject I have now arrived at the time when the Peas require examining every day. Pinch off all side shoots that may be growing, so that they may not stop the growth of the pod, and if the pods do not attain the largest possible size they are of little use for exhibition. I employ boxes to pack my Peas in, and I generally find the suitable boxes at the grocers or the tobacconists. If I am about to show a dish of small-podded Peas I find a cigar box is best; if they are large-podded Peas a box which has contained black lead is a useful size. Nothing is better for lining the boxes inside than Rhubarb leaves, also to cover the Peas with, as the leaves are cool in hot weather. Pack the pods in the boxes stalk end upwards, as they will travel very much better and show more bloom when taken out, also are better to handle than if packed upon their sides. When gathering the Peas for exhibition I always have the box with me, clip off the Peas, count them as I gather them, touching or handling only the stalk, and then I find the Peas come out of the boxes as fresh as though they had just been cut off the haulm.

The last ten days before the show I have found to be rather an anxious time, as in some seasons the Peas have been a little too forward, and at others I have had the misfortune to have the pods bruised with hailstones. Now as a preventive against hailstones or very powerful sun I make a stage each side of the row that I wish to preserve for exhibition, and I do it in the following simple way. Some strong stakes are procured, such as are used for Kidney Beans, say about 6 feet high for tall varieties and others in proportion. Point them and place them in the land about 6 feet apart, then nail some light stakes upon them from one end of the row to the other, and you will have a light stage to cover with calico a yard in width along the row. This I find at times to give great assistance in keeping my Peas from becoming too old or being bruised by hailstones. I may say the calico will last for several years. If the Peas were only for profit I should not be at the trouble and expense of shading them, but when cultivating them for exhibition I think nothing a trouble.

In these few notes I have indicated the principal part of my practice, with the exception of this—when the Pea haulm shows five pods set I take off the lead if they are for exhibition.—H. MARRIOTT.

#### PEONIA MOUTAN.

ENORMOUS supplies of flowers either on the plants or in a cut state are required in all homes, to meet which the energies of the gardener and the resources of the establishment are greatly taxed, as it is not enough to have the legitimate occupants of stoves and greenhouses giving their wealth of flowers in season, but plants hardy and out of season must be pressed into the service in order to maintain an unbroken supply of bright and sweet flowers through the winter and spring. Of this no one complains if only the means are equal to the demand, but when the means are few and the demand large it would be well to consider whether there is not more expected than can well under

the circumstances be forthcoming, which would save many a member of the craft much anxiety. When it, however, becomes a question of ransacking flower and shrubby borders in order to get plants for forcing, despoiling the garden of its brightest and most charming early-flowering plants, creating a blank that will then be glaring, it is questionable if the "game is worth the candle." It is truly astonishing to see the demand for and the uses to which flowers are now put, and yet we are asked to look upon the decline of gardening. Establishments noble and gentle are being reduced on every hand, the demand for the gardener and his wares is being discounted, which I think is not true, certainly not of floriculture, as the demand for flowers is decidedly an increasing one, pervading all classes.

So great has been the demand of late years for flowers at the dreary season that most everything with showy flowers amenable to forcing has been pressed into the service from the Christmas Rose to the Forget-me-not, bulbs without number, plants and shrubs without end, it not being a question of posies but of bouquets—"buckets," remarkable only for ungainliness—requiring as many flowers as were formerly required to fill all the vases. All is changed—then we only had decorations at party times; but now the table and other decorations are permanent we are advancing truly in floral if not in practical horticulture, hence I think the depression no evidence of its decadence. Chrysanthemums are over by this time, and we miss them much—their size, quaint forms, and rich colouring. Camellias, queen of the greenhouse, Azaleas of dazzling brightness, and the whole category of winter-flowering stove or greenhouse plants, with the usual plenitude of forced plants, lack the bold characteristic beauty of the Tree Peonies. The foliage is striking, the young growths really picturesque, and assume shades of violet and crimson to green, and the flowers are immense; there is nothing like them grown under glass so large and taking as to excite admiration, making indeed a grand display. Size renders the flowers conspicuous, and the shining glowing shades of colour give a brilliant effect. This of their effect indoors. Outdoors they are not very hardy, and the foliage and flowers are liable to be nipped by late frosts. Where, however, they succeed they are grand, and I have seen them as far north as York; indeed, there were fine bushes on the lawn where I first practised gardening over thirty years ago, which only had a good dressing of leaf soil every autumn, and had been raised by these annual dressings until the plants appeared on hillocks, and as the growths were pegged down they formed half balls nearly 12 feet across and were brilliant when in flower. Stakes and mats were ready to throw over them in case of frosts in spring, and the ground having a sharp incline to the south, and being sheltered to the north by shrubberies, they had every chance, much of the success being due to the copious supplies of liquid manure given when coming into bloom and through the summer. The soil were a heavy loam over clay.

There is one thing about these Peonies which I particularly wish to note—viz., their not doing well with the ordinary treatment given other plants in herbaceous or shrubby borders. It lives certainly and flowers sometimes, but it is not by any means remarkable. Certainly it is one of those plants that has been long subjected to careful and high culture, and when this is relaxed it recedes in vigour, floriferousness, and quality of bloom. Anyway, it is no use having it unless it is grown, for it will do nothing but disappoint; therefore afford deeply stirred well enriched soil, mulch so as to encourage free root-action, and feed liberally so as to secure stout growth and plump well-developed buds. Plants so treated for a few years will make a beautiful display in early summer, and if lifted and potted in November they make a grand display in the conservatory. They bear gentle forcing, doing well in a vinery or Peach house and forcing house with a temperature of 50° to 55° by artificial means, and 10° to 15° rise from sun heat.

Propagation is effected in various ways, but chiefly by grafting to which I allude, as in planting it is necessary to cover the graft or junction of the scion with the stock. A few good sorts are Jewel of Chusan, white; Comte de Rambutan, white, rosy centre; Dr. Bowring, rose; Van Houttei, rose, edged white; carnea plena, Carnation; Robert Fortune, scarlet; purpurea plena; and Elizabeth, scarlet. Rose a odorata, Arethusa, incarnata plena, and odorata Maria have fragrant flowers.—G. ABBEY.

### PRIZES FOR GARDEN PRODUCE.

As is well known, there are numbers of gardeners in almost every district who grow excellent produce for home requirements but make no special efforts in growing articles for public exhibitions. Large specimen plants are of no use for their purpose, neither are sensational bunches of Grapes nor big vegetables. They grow table and room-decorative plants admirably, also fruits and vegetables in variety and the most acceptable condition for the requirements of the family. Such men labour as well and as

worthily as those who have opportunities of preparing products to stage in competition for prizes that are offered in schedules. There are no prizes for hundreds of able plodding men, who are just as capable as those who are encouraged to exhibit, but their capacity is displayed in a different and not less useful manner. Cannot something be devised whereby these industrious home workers may have an opportunity afforded them to receive official approval?

As regards plants, the difficulty of the non-specimen growers competing at public exhibitions was surmounted by the introduction of "groups of plants arranged for effect" in a given space. The introduction of these classes in schedules has been a great success. I was, as far as I know, the first winner of prizes of this nature, and I have reason to know my advocacy of the extension of the principle has not been without effect. I would now ask if the time has not arrived when a further extension of the principle might be tried? If a space of 50 square feet or 100 square feet can be placed at the disposal of a gardener to occupy artistically with plants, cannot similar space be afforded, and at least as well occupied with miscellaneous garden produce—plants, flowers, fruits, vegetables, examples of vase decoration, hand and coat bouquets, wreaths—indeed, everything that a gardener can arrange as representing his work and practice? It seems to me that some highly creditable arrangements might be produced at once suggestive and artistic, the disposition of the exhibits to be left entirely to the competitors. The prizes should be determined for quality, not size of products, and effect. All fruit and vegetables should be named. If a trial were made of this plan, would it not impart variety and interest to shows? The first results would not be perfect, but improvements would naturally follow, and if these should be as marked as in the "effect groups" of plants, both societies, exhibitors, and the public would be gainers. Is this crude idea worthy of the consideration of the authorities of the coming provincial Royal Horticultural Show at Liverpool? and if so, will they offer good prizes for its development? Small amounts, as if provided as a sort of apology, would "settle" the matter at once, and it would be done with—for a time.—EX-EXHIBITOR.

### MUSCAT OF ALEXANDRIA AND BOWOOD MUSCAT.

YOUR correspondent "G. G." evidently believes that Bowood Muscat is a distinct variety from Muscat of Alexandria, and judging from his experience of the two he is entitled to consider them distinct. A variety of Muscat that sets its fruit under such difficulties as those detailed by "G. G." is worth increasing, and all growers should endeavour to obtain Bowood Muscat, when all doubts and fears attending the "setting" process will be finally dispelled.

"G. G." says that any grower could not fail to notice the difference between Bowood and the ordinary Muscat of Alexandria as grown at his place, but appears to think that a bunch of each variety laid side by side would not be easily, if at all, distinguished by even "better judges" than himself. The next sentence, however, rather contradicts this assertion regarding Bowood and Muscat of Alexandria, as "G. G." says "I have seen Muscat of Alexandria and Bowood Muscat shown in a collection of four varieties and carry off chief honours." Evidently this means that Bowood and Muscat of Alexandria were shown in the collection of four varieties referred to as distinct varieties, and were so accepted by the judges. From this it would seem that Bowood Muscat as grown by "G. G." is not so distinct in appearance from Muscat of Alexandria as it is to be seen elsewhere, and notably as it was shown as mentioned.

There seems considerable confusion and uncertainty about Bowood Muscat, but certainly "G. G.'s" statement regarding the good "set" obtained under adverse circumstances from a Vine which he has reason to believe is Bowood Muscat is calculated to make people wish that Bowood were more abundant, so that no fears regarding dull cold days and low temperature need perplex and annoy growers of Muscats who wish to grow a good "set." "G. G.'s" statement is certainly a very remarkable one, and if there are no other reasons which can be advanced for the success of the one Vine of Muscat and the failure of the other three, then it is to be hoped that he will not only increase the cultivation of the Bowood variety, but also kindly let others who may apply to him have a few eyes of it another season.

This is such an important difference that all should note it, and further remark would be interesting. I hope "G. G." will state if any artificial impregnation was resorted to in the above case; if so, if all were so treated; if the Bowood may not have been in proper condition for fertilising when attended to, and that the Muscat of Alexandria, being later, may have not been in condition for fertilisation at all, owing to the breakdown of the boiler after the Bowood had been impregnated either with or without artificial aid, but before the Muscat of Alexandria had arrived at the flowering

stage? The difference of ten or twelve days which "G. G." found in regard to Bowood and Muscat of Alexandria may account for the good "set" of the Bowood and the failure of the Muscat of Alexandria.

The Bowood may have been fertilised before the boiler broke down, and the Muscat of Alexandria may just have been timed to be in flower during the twenty-five days without fire heat. Consequently failure in one case and success in the other. Fuller details regarding the matter will no doubt be welcome to more than—  
A READER.

### CYPRIPEDIUM LEUCORRHODUM.

THIS is one of the numerous hybrid *Cypripediums* raised in Messrs. Veitch & Sons' Chelsea nursery, and though it is about ten years since the cross was made, the plant did not flower until last year. It resulted from crossing *C. Roezli* and *C. Schlumi album*, and is curiously intermediate between the parents, the flowers being of a soft delicate rosy

Fig. 21.—*Cypripedium leucorrhodum*.

tint, nearly white in some parts, with a full rounded slipper-like lip. The plant is very strong in growth, producing leaves of considerable length, broad, and bright green. Now it has reached the flowering stage it will probably produce blooms every season, and it is somewhat strange that some exceedingly floriferous hybrids have required so long a time to reach that stage as seedlings.

The two species named have been employed with others in the production of several beautiful hybrids, of which may be mentioned *C. alborpurpureum*, *C. cardinale*, *C. porpyreum*, *C. Sedeni*, and *C. Sedeni eandibulum*, all possessing a general resemblance to each other. *C. Sedeni* is one of the most useful hybrids hitherto obtained, and *C. cardinale* is very handsome. A charming group is being formed, which is often referred to as the "Sedeni family" with peculiar appropriateness.

### SMALL GARDENS.

It is becoming generally recognised that we must not always expect to find the best gardening in the largest establishments, not because those in charge are deficient in ability, but because too often they have not the means requisite to keep an extensive garden with numerous glass houses for fruit and plants in the condition that they desire. When such a garden is adequately supported, as happily we can still see in many cases,

we expect to find the art of the horticulturist in perfection, and we are seldom disappointed. When, however, a competent practitioner has charge of a comparatively small garden he often has greater facilities for insuring success than where his attention is spread over a wider area and he has to entrust the execution of important details to subordinates. In a small garden everything comes directly under the eye of the chief, and the results are materially influenced by his knowledge and experience. There are now innumerable gardens around the metropolis and large cities which well deserve the title "model gardens" for the admirable examples they present of good all-round practice, or in other instances they have a local fame for specialties. Many a useful lesson can be learned in such places; some first-rate gardeners have there gained the rudiments of an education that they have subsequently applied to excellent purpose. There is a strong inclination amongst young men to serve in large gardens, but they often learn less in two or three years' service in such establishments than they can in twelve months under an able man in a smaller garden where they see the whole routine. It is also often more necessary to use a man's wits in economising the means or material at command to produce the best results in a garden of moderate extent than in one where there is every convenience that wealth can procure. A greater interest must also be felt when the attention is more closely concentrated upon particular objects, and a much clearer knowledge of the peculiar requirements of either flowers, fruits, or vegetables is so obtained. I have visited gardens of all descriptions and sizes, and have generally felt a greater satisfaction with those of moderate extent. I have also worked in both large and small gardens, and with but one or two exceptions I gained far more useful knowledge from the latter than the former.

These few lines have been prompted by a conversation I recently had with a young gardener whose great desire was to obtain admission into a nobleman's garden, and he had refused several good offers of situations in less important establishments. He preferred waiting, and perhaps wasting some months in anticipation of gratifying his fancy to taking a place that would probably have proved far more beneficial to him. I know there are many more like the one mentioned, and who think that, without some recommendation from a nobleman's gardener, there is not much chance of obtaining a good head place themselves. Some such feeling has prevailed, but it is being lessened, and employers seek for something more than this uncertain kind of testimonial. The fact is, the large gardens are decreasing in numbers and importance, while the smaller gardens attached to suburban villas and wealthy merchants' residences are increasing, and there is in consequence much more room for employment in these than the others. All young men who are waiting in nurseries for places and regretting their ill fortune would do well to consider this matter carefully.—AN OLD GARDENER.

### A COMPARISON OF MANURES FOR THE GARDEN AND ORCHARD.

[A paper by Professor G. C. Caldwell, Ithaca, New York, read before the Massachusetts Horticultural Society.]

(Continued from page 91.)

As already said, decaying vegetable or animal matter in the soil makes humus, or vegetable mould. This common ingredient of all arable soils is not necessary for plant growth; for, on a small scale, in pot culture good crops have been obtained in a soil as white as snow, and therefore quite free from any humus, but containing all the real plant nutrients that have been mentioned. But that this humus is an important ingredient of a fertile soil no one can doubt. Given two soils equally rich in nitrogen, potash, phosphoric acid, lime, and all such matters, but of which one is poor in humus and the other rich in it, but yet not so excessively rich as a bog or a muck bed, there is not a farmer or gardener who knows soils who would not give more for the soil rich in humus than for the other. In the course of the decay of these vegetable matters several acid substances are formed, and chiefly carbonic acid. These acids act on the large quantity of difficultly soluble plant food in every arable soil of fair quality, and aid in bringing it into solution, and thus within easy reach of the plant. Few farmers realise what a large native stock of crop food they have in their soils. In the case of a fertile soil from a Western State, analysed some time ago in Germany, there would be, by calculation from the analysis, in one acre of it, and within a foot from the surface, 2400 lbs. of phosphoric acid and 7000 lbs. of potash. But nobody in New England has a Western prairie soil on his farm; nevertheless, judging from analyses of twenty-five different soils of average quality by the same chemist, we may say that an average good soil will contain, within 12 inches from the surface, and therefore accessible to the crops, and fit for plant food if any means can be provided for bringing it into solution, 1500 lbs. of phosphoric acid, 1500 lbs. of potash, and over 1750 lbs. of lime. Compare these amounts with those that a crop takes up, and one can realise more fully the native value of a good soil. The quantities of phosphoric acid and potash in pounds, per acre, required by some of the more common crops are shown in the following table:—

		Phosphoric	
		Acid.	Potash.
Corn, 50 bushels and its stover	.. .. .	50	70
Potatoes, 150 bushels	.. .. .	15	50
Wheat, 25 bushels and straw	.. .. .	18	25
Apples	.. .. .	20	50

These native supplies, then, so very much larger than the yearly demands of the crops, if we can bring them into use only a little every year, may go far towards producing these crops for the farmer or gardener. If humus by its decay helps to bring about the solution of these supplies

then it must be useful, since all such plant food must be taken up in solution.

That the carbonic acid, which is one of the main products of the decay of humus, does in some way favour vegetable growth is very neatly illustrated by an experiment performed many years ago by Stoeckhardt. Three deep glass vessels, two of which had holes pierced through the bottom, were filled with soil, and Peas were planted; through the hole in the bottom of one of the vessels and up through the soil there was passed every day a certain quantity of air, and up through the soil of another of the vessels a mixture of air and carbonic acid; the third vessel was left to itself, and the condition of things in it was about the same as in an ordinary soil with a very compact and impervious subsoil. The weight of dried crop produced in the third vessel without any circulation of air was about 90 grains, in the soil through which air was circulated 162 grains, and in the soil through which air and carbonic acid were circulated 190 grains. In some way the carbonic acid along with the air helped the crop amazingly, more than doubling it. This was not necessarily because the plant fed on this carbonic acid directly to supply itself with that most important element, carbon. It has been proved over and over again that vegetation supplies itself with carbon, at least mostly, if not entirely, from the carbonic acid of the atmosphere. The fair presumption is that the carbonic acid passed through the soil brought more plant food into solution, and so the crop was more liberally provided with this means of growth.

In support of this presumption we have the fact demonstrated also by Stoeckhardt, that the very soil which produced the largest crop, and therefore had yielded up the largest amount of dissolved plant food, still contained the largest amount of soluble plant food, ready for the next crop. The quantity of such soluble food was, in the soil of the closed cylinder without any circulation of air, 22 grains; in the cylinder furnished only with air, 43 grains; and in the soil to which both air and carbonic acid were supplied, 60 grains.

You will have noticed that the second soil, receiving only air, also gave a notable increase both of crop, and of soluble plant food left for the next crop. On first thought this result would appear to conflict with the explanation given of the increased crop in the third soil, that it was due to the carbonic acid passed through that soil along with the air. But there is not necessarily disagreement here; it is quite reasonable to suppose that the humus in this soil, together with the oxygen of the air that was circulated freely through it, produced the same effect and in the same way as was produced by the carbonic acid ready formed in the third soil. The formation of carbonic acid from the humus can take place only in the presence of oxygen, and the more liberal the supply of oxygen the larger will be the production of carbonic acid from a given quantity of humus. In this second soil we had, as in all the others, the ordinary quantity of humus; the supply of air, with its one-fifth part of oxygen, was liberal; carbonic acid must have been produced freely; and it would have been strange if there had been no increase of crop. Such a result would have tended to disprove just what we are seeking to prove, that the humus does a good work for the farmer by the carbonic acid given off in the soil as it decays, or oxidises, which two terms mean much the same thing.

Another experiment shows in a no less striking manner the part that humus may take in bringing plant food into solution: a sample of a sandy loam was compared with another portion of the same soil to which some humus had been added; in the course of the summer months, while a crop was growing vigorously on these soils, the quantities of potash that became soluble in the two soils were as 366 parts in the soil poor in humus to 574 parts in the other; the quantities of plant substance produced in the two cases were 5040 and 9800 parts.

(To be continued.)

### STRAWBERRY PLANTS IN WINTER.

"W. S.," page 87, objects to my statement that the practice of plunging the pots in an upright position, either in leaves or ashes in damp situations and in wet winters, often leads to disastrous results by the plants being kept in a constantly wet and sodden state during the period of rest, when comparative dryness should be their condition; and he points out to me that "there is no necessity for this being so, if the site selected for that purpose be higher than the ground surrounding it." It is quite evident that "W. S." does not comprehend my meaning. What I wished to show was that the rainfall in wet winters in this climate, especially when the small amount of evaporation is taken into consideration, is much greater than is beneficial to Strawberry plants in pots prepared for early forcing. I freely admit that in elevated and breezy positions where the evaporation is great no serious evils may result, but the case is very different in low-lying damp localities, where the dryness of the air is not sufficient to keep the plants plunged in an upright position in a healthy condition. The usual practice in preparing Strawberry plants for forcing is not only to pot them in strong loam, but also to ram the soil down firmly. Under these conditions rain cannot freely pass through the soil, and in changeable frosty weather the space, as I explained before, between the surface of the soil and the rim of the pot frequently becomes a mass of ice and the plants suffer considerably. "Such a condition cannot, I venture to say, be the best winter quarters for Strawberry plants in pots intended for early forcing." They may be covered lightly with dry fern, and so long as the fern continues dry and can be removed daily no serious injury may accrue, although the labour and inconvenience is great; but at times the covering cannot be removed for days or even weeks together, when serious injury must result. I have tried both methods not only for fourteen, but for nearly forty years, and

I have no hesitation in saying that the plan of stacking them on their sides in ash heaps is the most safe, economical, and satisfactory.

"W. S." expresses a wish to know "upon what grounds I arrive at the strange conclusion that the condition of Strawberry plants in pots which are laid on their sides in ashes during the winter and early spring months, is more nearly like that to which they are naturally accustomed." My reasons for forming this conclusion are simply these. I have found by experience that after excessively wet winters not only do Strawberry plants in pots plunged in an upright position suffer considerably, but those in the open garden do so likewise, unless the position be elevated and comparatively dry. If we look to the States of Virginia and Carolina, whence came the Strawberries from which our cultivated species are chiefly descended, and where they are said to flourish in their native luxuriance, the winter and spring seasons are not only more severe than ours, but the rainfall during those seasons is less, while the air is considerably drier. Although the rainfall during the growing season is greater than with us, yet the evaporation and consequent dryness in such an elevated region, which is said to range chiefly between 500 and 700 feet above the level of the sea, must be much greater than we experience in this humid climate. The other vegetable products of these States also show most plainly what the conditions of climate are there, and wherein they differ to those of this country. These are some of the reasons which induced me to write the paragraph to which "W. S." objects, and these are also my reasons for concluding that Strawberry plants arranged as I have advocated are placed in more natural conditions than when arranged as "W. S." prefers, and I venture to think they are "quite in harmony with those conditions under which the plant flourishes naturally."

In conclusion, I cannot forbear asking "W. S." how he arrives at the somewhat strange conclusion "that the Strawberry plant in gardens, during the resting period, receives direct from the clouds three times the amount of water at the roots that it does at any other time?" I fear his rainfall tables are somewhat inaccurate.—T. CHALLIS.

It has been finally arranged by the Council of the ROYAL HORTICULTURAL SOCIETY TO HOLD A PROVINCIAL SHOW AT LIVERPOOL in the ensuing summer. Through the liberality of the Worshipful the Mayor and Corporation of Liverpool, the Botanic Garden, and so much of the Wavertree Park as may be necessary, have been placed at the service of the Royal Horticultural Society, and no better place could have been found. The Show will be opened on Tuesday the 29th June, and will be closed on the evening of Monday the 5th July.

— AN obvious misprint occurred in the report of the UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY on page 110, still it is advisable to correct it. Instead of the contribution of 2s. to the deposit fund annually it should be monthly; the other contributions are correctly stated in the report.

— "J. R. S. C." writes:—"Some one asks about CATCHING MOTHS. I presume he means moths in general, not those of the clothes moth group. Some sweet compound is effectual—treacle better than sugar, duly diluted and flavoured with rum or aniseed, some say; but all these are uncertain at particular times."

— IN the report of Mr. J. Pavey's paper on the CULTURE OF HARDY FRUIT TREES, read at the Lee, Blackbeath, and Lewisham Horticultural Meeting on the 29th ult., it is stated that Mr. Pavey advised dissolving 8 lbs. of softsoap in 4 gallons of boiling water for the destruction of American blight. This was a mistake; it should be 2 lbs. of the softsoap to the quantity of water stated.

— AT the fortnightly meeting of the HUDDERSFIELD PAXTON SOCIETY, the President, Mr. G. W. Rhodes, in the chair, Mr. C. Smedley gave an excellent paper on the Amaryllis. The essayist, a good cultivator of this class of plants, was listened to most attentively. An interesting discussion followed. Mr. Jarman, Vice-President, described some splendid hybrids he saw at Messrs. Veitch & Sons' last season. A hearty vote of thanks to the essayist and Chairman brought a very pleasant evening to a close. On February 27th Mr. F. Milan, a practical hot-water engineer will give a paper on "Domestic Hot-water Supply."

— "M." WRITES, "A year or two ago the pretty bulbous plant FREESIA REFRACTA ALBA was comparatively scarce, but it is now

much more frequently grown, and the flowers may be seen in many florists' windows, especially in Covent Garden Market. The flowers are white, delightfully fragrant, and beautiful in bouquets, though they are not very durable. It is particularly well adapted for culture in pots, and a few dozen bulbs would be a serviceable addition to any collection."

— WE learn that MR. J. JOHNSTONE has resigned his charge of the Baby Hall Gardens, the residence of W. Pilkington, Esq., after having the care of them for nine years. A report of these Gardens appeared in our pages a few years ago, and their condition generally testify to his ability as a practical gardener. We hope that he will soon find another suitable position.

— GARDENING APPOINTMENT — Mr. George Easton, late gardener to C. R. Hodgson, Esq., Copt Hall, Hendon, has been appointed gardener to Wm. More Molyneux, Esq., Losely Park, Guildford, Surrey.

— THE monthly meeting of the BELGIAN SYNDICATE OF HORTICULTURISTS was held in the Casino, Ghent, on the 8th inst., Mr. J. Closen of Liège presiding. M. Ch. Van Geert of Antwerp was Secretary, and the following were present:—MM. E. Vervaeet, Ph. Blancquaert, Jules Hye, A. Desmet, L. Desmet Duvivier, A. Rosseels, and B. Spae. Certificates of merit were awarded for the following plants:—*Echmea spectabilis*, from M. Ad. D'Haene; *Anthurium leodinense*, from MM. Jacob Mackoy and Cie.; *Cypripedium marmorophyllum*, from M. E. Pynaert Van Geert; and *Begonia Gloire de Sceaux*, from M. A. Van Geert. A cultural certificate was awarded to M. B. Spae for *Cocis Yatai*, and honourable mention for a seedling *Clivia*, Jules Hye, from M. Spae Vandermeulen; *Lycaste Skinneri alba*, from M. James Bray; and a seedling *Clivia*, from M. E. Pynaert Van Geert. Honourable mention for good culture was also accorded to *Dracæna Lindenii*, from MM. Blancquaert et Vermeire.

— AT a recent meeting of the members of the WAKEFIELD PAXTON SOCIETY, Councillor Milnes presided, and Mr. Hudson, gardener at Sandal Grange, was in the vice-chair. There was about an average attendance. Mr. J. A. Mann, gardener to Mr. D. B. Kendell, J.P., Manor House, Heath, read a short but most interesting paper on "The Bouvardia," a beautiful winter-blooming stove plant. Mr. Mann, who has for some years past been a successful grower of the Bouvardia, fully and clearly explained his mode of growing and propagating the plant, and stated that by the mode of treatment he recommended he always produced fine large plants and an abundance of sweet and beautiful bloom at a season when flowers are usually very scarce. He said there are about thirty-four varieties, and he named several which he had, by experience, proved to be good sorts. A number of questions were put to Mr. Mann by Messrs. Hudson, Preston, Garnett, and Brown, and the prompt and clear manner in which they were answered showed that Mr. Mann was thoroughly acquainted with his subject. On the motion of Mr. Hudson, seconded by Mr. J. Lee (St. John's), and supported by other members, a very hearty vote of thanks was accorded to Mr. Mann for his maiden essay, and a hope was expressed that this would not be his last appearance before the members of the Society in the character of an essayist.

— AN American correspondent sends the following cutting from the *New York Tribune*:—"Mr. G. Cowing, the Indiana horticulturist, had several trees of the KIEFFER PEAR killed by the frosts of last winter, though none of his other varieties were injured. He quotes 'many of the best judges of fruit throughout the country' as testifying that this sort for table use is 'hardly passable,' and adds, in the *Indiana Farmer*:—"It appears to grow well and produce abundant crops of showy insipid fruit in a few places in New Jersey and in some portions of the south, but the prominence it attained in the middle and northern States was mainly due to a liberal use of printers' ink."

— IN the volume devoted to the BOTANICAL RESULTS OF THE "CHALLENGER" EXPEDITION, which is just issued from the pen of Mr. B. Hemsley, there is much of an interesting character, as can be judged from the following extract relating to the DISTRIBUTION OF PLANTS:—"The seeds of many almost ubiquitous sand-binding grasses may be reckoned among those which are cast ashore in a vital condition, and we assume that these grasses are amongst the first flowering plants to obtain a footing. Other herbaceous plants met with in the earliest stage of such an insular flora are *Portulaca*, *Sesuvium*, *Canavalia obtusifolia*, *Ipomœa hloba* (*I. pes-capræ*); all of which seem to possess an unlimited power of colonisation. Moreover, they provide the conditions necessary for other plants to be able to establish themselves. Among the early

shrubby occupants, *Suriana maritima*, *Pomphix acidula*, *Scaevola Koenigii*, and *Tournefortia argentea* are prominent, being found on the most remote islets of the Pacific and Indian Oceans within the tropical and sub-tropical zones. Where there are muddy shores, there the various Mangroves (*Rhizophora*, *Bruguiera*, *Avicennia*, *Vitex*, &c.) take possession. Among the first real trees are *Heritiera littoralis*, *Hibiscus tiliaceus*, and *Barringtonia speciosa*, together with Screw Pines. After this nucleus of a flora has been formed, it is comparatively easy for other arrivals to establish themselves; and every addition in a measure helps to provide the conditions for a still more varied vegetation. And he concludes:—"It may be safely assumed, therefore, that if oceanic currents and birds have not been the means of dispersing a large number of species of plants, and it is not certain that they have not, they are certainly the most important agents in stocking islands, for without their action the numerous remote coral islands, at least, would still be utterly devoid of phanerogamic vegetation, and consequently uninhabitable."

— PRESIDENT BARRY in his opening address at the annual meeting of the WESTERN NEW YORK HORTICULTURAL SOCIETY gave the useful reminder that where Apples, Pears, and other fruits are sorted, and only the best specimens sent to market, good prices are secured, and if no other grade were marketed there would be no complaint of surplus, and the gross income would be as great. Our fruit crops may be doubled in value by a few years of first-class culture—soil made rich; trees carefully pruned; fruit thinned, if necessary; gathered carefully by hand-picking; honestly packed; the whole business systematised, and conducted in the most economic manner. In some instances last season prices were lower than ever known before, especially about Rochester, where the supply was large. As a whole, however, the fruit business was more satisfactory than ordinary farming.

— AT the same meeting, referring to the APPLICATION OF LIME AND SALT TO SOILS, Dr. Caldwell quoted the saying that application of lime tends to make the father rich and the son poor, and the same may be remarked of salt. It loosens fertility locked in the soil, and renders it available, but does not add fertility. There are, however, very few soils that have not lime in abundance, and also salt. Salt is largely applied to compost heaps, but it is not so good an absorbent as common earth, and cannot be compared with plaster or gypsum, which does prevent the escape of ammonia. Salt in the compost heap renders the same service as the application of water; it keeps the manure moist, and thus prevents heating and firefang. Several members thought that application of salt to Wheat fields stiffens and brightens the straw, and causes the Wheat to be lighter in colour. Salt also retards ripening in dry weather, and has been sown upon Barley with benefit. Dr. Hexamer said he applied salt freely to certain rows of Asparagus in a large patch without any visible result; he considers that salt is of no benefit to this plant. Mr. Caywood gets no Quinces unless he applies salt freely. Other members said they apply salt to Plums and Pears with good result.

— ANALYSES OF PLANTS.—"J. L. B." writes:—"Will you please insert the following in your next issue, and will you kindly publish any tables that may be sent in reply? Will someone give me tables of the composition of plants (from analyses), particularly those of the *Chrysanthemum* and the *Rose*? I may add that I have the 'Gardeners' Assistant,' in which there are several given, and any that that work does not contain I shall be very glad to have, or to know where I can obtain them."

— ORANGE CULTURE IN NEW SOUTH WALES.—In no part of the world are Oranges grown to such perfection or with more ease than in New South Wales. Anyone with a small garden can grow a few Orange trees, the rearing of which occasions far less trouble than that of the Currant trees or Gooseberry bushes in an English cottage garden.

#### THOUGHTS ON CURRENT TOPICS.

FROM what I have heard I think Mr. Bardney surprised not a few persons by his advocacy of 12 per cent. of lime as a suitable proportion to Vine borders. It is a large quantity no doubt, but it is a question if it is excessive for Vine borders made of limeless soil, and have besides been much enriched with repeated top-dressings of manure, producing much humus. I believe that soil considered satisfactorily fertile for agricultural purposes contains, or should contain, 6 per cent. of carbonate of lime, and may contain a good deal more. What does this mean? It means that if the soil contains no lime a very large application is needed to enable 6 per cent. of carbonate of lime to be added; 300 bushels of slaked lime per acre and mixed with the soil to a depth of 6 inches will be only 1 per cent. That is obviously quite inadequate for Vines.

A POSSIBLE danger of using lime excessively is pointed out by "A. L. G." on page 62; and he quotes a passage from a work on chemistry in opposition to the teaching of Mr. Bardney's Cabbage bed. The evidence afforded by that practice is in my opinion valuable. As the late "Single-handed" often pointed out, the soil immediately in question is the best laboratory, and when the results of careful practice are in conflict with the teaching of books the books are the least reliable, because authors cannot possibly have regard to special local governing influences, their reasoning being necessarily founded on general principles. I have applied lime at the rate of 700 bushels an acre with the most marked benefit to the crops; and if I found a Vine border made of limeless loam, and also rich in humus by continuous top-dressings of manure, I should quickly apply lime in still greater quantity.

WE have also to consider what Mr. Bardney suggests, the readiness with which lime is washed out of the soil. Lampadius' experiment is conclusive on this point. He added lime to a plot of ground in proportion to 1.19 per cent. of the whole, and by the action of the rains alone it diminished in one year to 0.89, the next 0.52, and the third 0.24. Well-drained Vine borders often get five times the quantity of water that falls from the clouds in the same area in the district, and the lime is more rapidly removed; nor is this all, for in soils rich in animal and vegetable matter combinations occur that accelerate the removal of lime by filtration. Acids, the result of oxidation, in rich soil combine with carbonate of lime and release carbonic acid for plants, and a portion perhaps to be wasted. This, however, is of trifling importance in comparison with the action of lime on nitrogenous matter in yielding ammonia, and this does not escape in any material quantity, but is stored in the soil for use. This is what science teaches and practice confirms.

I ONCE took charge of a garden that had been heavily manured for say a century; it was a mass of humus, yet unproductive. For the first two years not a particle of manure was dug into the quarters, but lime was supplied instead, and for seven years no manure was given to the bush fruit quarters. The change to fertility was marvellous, and the garden is now as productive as anyone can desire. There is a vast amount of plant food locked up in the land of overrich gardens which lime can liberate for appropriation by crops. Poor land, including Vine borders (which ought not to be poor) may be injured by the too free use of lime, but rich land is improved by liberal applications if it is practically limeless. It is difficult to deal with a great subject like this in a few short paragraphs, which only represent passing thoughts, not exhaustive essays.

MR. TAYLOR will, I hope, excuse me saying that I fail to see anything in his note that satisfactorily answers my proposition of the Gros Colman Vine being so constituted as to require more water for the sustenance of its foliage than most other varieties do. I readily admit the excellence of his Grapes, also his competency in judging as to when Vines in pots need water. All his writings indicate him to be most careful in what many persons call "small details," but watering and ventilation are "great factors" in contributing to success. Putting aside the premature discolouration of the foliage of his Gros Colman, I should require to know the relative size of the Vines before attaching weight to what he says on page 67. I can very well understand a large Vine of Muscat of Alexandria requiring more water than a smaller one of Gros Colman; but I cannot understand that as much moisture evaporates from a small as from a large leaf, both being grown under the same conditions. I say that when Vine leaves turn brown and shrivel at the edges, it is in nine cases out of ten the result of moisture escaping from the leaves faster than it is supplied to them from the soil by imbibition of the roots. Moisture in the atmosphere will arrest evaporation, so will shade from the sun; and I cannot help thinking it better to adopt either one or other of the methods than to permit the foliage to fail at a critical time. I do not base my proposition on theory alone, but on actual results on a rather large scale. I repeat that strong free-growing Vines of Gros Colman require more water than most other Vines do, and this afforded (or failing it, light shade applied), the leaves will remain fresh the longer. No doubt if something good is mixed with the water it is better for the Vines; but I doubt very much if it was a lack of potash that caused the leafstalks of Mr. Taylor's Gros Colman to droop while the leaves remained rigid. It was primarily the loss of moisture, and though the effects may not have been immediately visible on the leaves they would be disclosed in a few days. The leaves and young growths of Vines contain only a mere trace of potash, carbonate of lime being by far the greater mineral agent there, amounting to 4.8300 against 1.1700, out of a total of 7.5014. However misleading may be the appearance of a man's hand as indicative of health, I do not think the above figures are very seriously misleading, and they are submitted for what they are worth.

I READ with pleasure Mr. S. Castle's notes on Vines, he appears so earnest and so honest, being apparently as ready to admit a failure as record a success. I always think of him as a man who will succeed if success can be attained by strenuous effort. Not that he stands alone in this. There are others as earnest as he is, but not many so ready to admit they have something to learn. In his last communication (page 90) Mr. Castle expressed a fear to apply potash to Vines lest it should impede the ripening of the wood. I believe it will not have that effect. It is an element in solidification, nitrogenous manures contributing to extension, and thus having a tendency, if applied late, to retard maturation. For instance: Sulphate of ammonia or nitrate of soda are excellent applied

after Grapes are stoned, for feeding the fruit, but not after colouring. The heaviest crops of Grapes I have ever seen were supported with these fertilisers. The last named is slightly the quicker in action, the former more lasting in effect. But neither should be used in the absence of a due proportion of carbonate and phosphate of lime, also potash, in the soil, or the border will not long remain satisfactorily fertile.

AS I cannot always be praising, but must have a victim by way of a change, "J. M." must be the doomed individual, or rather one of the plants he praises so highly must be taken down a degree or two, as I think it is overrated. In his notes on choice and useful Palms, on page 40, your correspondent says, "Seafortbia elegans grows in a semi-dark place, and bears confinement in entrance halls better than any plant I can name;" and further goes on to say, the Palm "above all others that deserves to be grown in quantity is Seafortbia elegans." This double-barrelled recommendation is also rather too strong in my opinion. I do not attach any particular importance to a handsome specimen of *Phoenix reclinata* that has been in a room for seven years and remains as handsome as ever; but I do think a little weight must be given to the experience of one of the best and most extensive growers of Palms in the kingdom, and who would gladly grow Seaforthias but for the fact that, as he said, "Kentias were driving them out of the market, and except as regards a few that may be wanted as tall specimens, will drive them out of the kingdom." He had at least a thousand Kentias to a dozen Seaforthias, the former of a rich deep green hue, the latter washy in comparison, and somewhat of a "thripy" appearance. For richness of colour and elegance combined with a certain massiveness, Kentias far outdistance Seaforthias. If "J. M." will try them fairly I feel certain, if he gives me a sound castigation next week for this tender allusion, that he will repent of his severity before he is five years older. I await results.

MR. PETTIGREW conveys a really useful hint on page 39 on covering the back walls of vineries attractively and usefully. If anyone had asked me what to plant in such shaded positions my reply would have been white Camellias. I know a range of Peach houses in which the fruit is grown for sale, and grown well, but the white Camellia blooms produced by plants covering the back wall exceed the Peaches in value. These are forced to be ready in June, and the treatment brings the Camellias in plentifully for Christmas; but these plants are of rather slow growth, Lemons being far quicker. I remember seeing the back wall of a lofty vinery covered with handsome Lemons years ago—so long since that I had forgotten the circumstance till reminded of it by the interesting letter on the page quoted.

THE Reading Hero Potato has been under discussion and has come out of it bravely. I am able to confirm what is said of its excellence. Grown on a medium soil, the crop was good and the quality of the tubers of the first order. The same I can with equal accuracy say of the Ashtop Fluke in reply to Mr. Murphy (page 62). The Hero may be described as a full, the others as a delicately flavoured tuber. But can your correspondent point out in what respect it differs from the old Lapstone Kidney? With me this pair are as like as two peas. Not a few old-fashioned Potato connoisseurs regard the Lapstone as unsurpassed in quality, but liable to disease. I am not positive that my Lapstones were obtained true, but I know they are good, and the Ashtop Fluke is just like them.

A SLOUGH correspondent asks if either I or anyone else can suggest a remedy for the clubbing of Broccoli plants. The absence of chalk in the soil is a primary cause of the clubbing of the roots of plants. The quantity of lime mentioned—namely, one bushel to a perch—is of little or no use in arresting the evil. Let four times the quantity be applied to a plot of ground. Puddling the roots of plants in clay alone is of small service, but a mixture of equal parts of clay, soot, and lime, dissolving a wineglassful of petroleum in a gallon of the puddle, will be found more effectual. The addition of ashes might aggravate the evil by rendering the gravelly soil more porous and drier. Lime has an opening effect on heavy land, but an opposite effect on some light soils, rendering them closer and more retentive of moisture. This is my thought on the subject. I shall be glad to hear what others may have to say on the clubbing of plants.

I AM glad rather than otherwise if I did not put the exact construction "J. T. S." intended in his article on the influence of the "virgin lands" of the far west threatening the ruin of British agriculture, because of the thoughtful yet spirited reply on page 87. I did not intend to suggest that your correspondent was frightened by foreign competition; but that many persons are in such a state of alarm that paralyzes effort is beyond a doubt. Sad it is to see this giving up and adopting a policy of despair. It is clear that "J. T. S.," whoever he is, and whatever he is engaged in, does not intend to fail, and I venture to say he will not fail if he is vouchsafed the blessing of health.

#### ADDENDA.

THE above paragraphs were written long before the last issue of the Journal was published, the comments on the following extract being penned since.

"I HAVE for some years been accustomed to review at the commencement of each year the principal points in connection with our favourite pursuit which have struck me during the past year; and although the same course has been adopted by your correspondent who signs himself

'A Thinker'—are not most of us thinkers?—yet I do not depart from my usual custom, as we do not travel on the same lines or discuss the same subjects. My task is much more commonplace, and in truth I have to deal more with a narration of facts than the discussion of questions which do not fall within my ken. I am but an 'individual' who, in a humble way, tries to bring forward some facts which, ere the year grows much older, may as well be gathered up, and not forgotten. I have written 'individual,' to which Mr. Harrison Weir objects rightly. One is reminded of the story of O'Connell, whose vocabulary of abuse was very extensive, and who undertook that he would silence one of the Dublin 'fish fags,' who were as celebrated in this way as the Billingsgate fish wives. After they had been firing away at each other for some time, and the 'Liberator' began to be in despair, he turned to his opponent and in thundering tones cried out, 'You're nothing but an individual.' This finished the battle. She succumbed, and left O'Connell victor." When I read that paragraph on page 72 I naturally thought the repeated mention of a simple English word and the extraction of it from O'Connell's "vocabulary of abuse" was a rebuke directed to myself, and so did other persons, as I have ample evidence. They thought, as I did, that it was going rather beyond a joke. Still, as I was reluctant to retort hastily I sent a short paragraph, which appeared on page 85, with the sole object of affording opportunity for any explanation that "D., Deal," might care to make. This is given on page 105, and frankly accepted, as no one can know so well as the writer of the paragraph that the words did not in "any way" apply to me. I thank your correspondent, and would assure him that I can endure, even enjoy, good-humoured criticism, and I believe I have my share.

BUT this O'Connell episode is so good in its way that it ought not to be passed, and there appears to be so many versions of it that I have endeavoured to trace its origin. I really do not take the late Mr. Daniel O'Connell as my model in conduct, and I am bound to enter a gentle protest against any even seeming attempt to include the familiar and good old English word "individual" into the "vocabulary of abuse." The Dictionary gives the meaning of the offending word, and of "abuse" also, to which anyone can turn who chooses to do so. O'Connell never used the word at all in his celebrated contest with Mrs. Moriarty when she tried to sell him a walking-stick from her stall of "notions," the price of which he disputed. Then followed the war of words first recorded by Mr. D. O. Maddyn. As those on the "Liberator's" side were avowedly humorous, they can be quoted without any impropriety, and will be amusing at least to several gardeners as a relief from hard digging and dry reading. "One and sixpence for a stick that cost you twopence!" shouted the "Liberator;" "why, you're no better than an impostor." Then, in reply to the dame's hot retort, exclaimed, "Keep a civil tongue in your head, you old *diagonal*; don't be in a passion, you ancient *radius*; don't choke yourself, you *paral-lelogram*. You will deny you have an *hypothenuse* in your house next; but you can't deny the charge, you miserable *sub-multiple* of a *duplicate ratio*; you inimitable *periphery*; you convicted *perpendicular*, trembling with guilt to the extremity of your *corollaries*. You are found out, you *rectilineal antecedent* and abandoned *similitude of the bisection of a vortex*."

THERE is the celebrated "vocabulary." I do not object to be associated with the "Liberator," especially in such good company as "D., Deal." O'Connell may have been misguiding by an exuberant imagination, but he was, I think, an honest man, and for every honest man I have respect, however widely we may differ in our views and opinions. I have taken good advice on the subject of my philological assumption, and remain content. If I am aware that any individual objects to be referred to in any particular manner, I shall respect his objection, and I fail to see what more can be fairly required. "D., Deal," and myself are both engaged in the same work and with the same object. We differ in our views no doubt on some things, which is, perhaps, well, for if all thought alike and wrote alike the Journal would soon be very tame reading. We will now start afresh. There is plenty of room for all to proceed without any serious jostling in the "republic of letters."

It is very evident I have "caught a tartar" in "Utilitarian." It is pretty clear, too, he is more "advanced" than I am, and would express himself more strongly against inequalities in taxation as between trading gentlemen, who profit by their luxuries, and men who labour for the means to live, if he were not "in the business." I see he does not understand the routine of determining assessments. I wonder if he knows that according to law the ground in nurseries and market gardens is exempt from taxation? the "houses" only can be valued, not the land; but is not much of it assessed even more highly than the ground from which wealthy individuals sell produce? That is the question, and I believe that in instances innumerable nurserymen and market gardeners are flagrantly overrated. Your correspondent fails to distinguish between luxuries and necessities, hence there is no common ground for discussion. The question as to the rating of allotments is not in dispute, because they are rented on the average at the least 10 per cent. higher than agricultural land, rates included in the rent, and that is surely a sufficient answer to his question. The question of an allotment holder, or anyone else, consuming or selling his produce is perfectly immaterial. It is the "possession" of the value, not its disbursement, on which taxes are levied. If "Utilitarian" earned £500 a year, spent every penny of it in charity, and got credit for his own support, he would have to pay income tax all the same. The real question is the relative amount of assessment of

*bonâ fide* traders and private gentlemen who compete with them. So long as these enjoyed their luxuries no one begrudged them their privileges, but when they enter the lists as competitors in trade under special and advantageous circumstances, regular traders, nurserymen, and market gardeners feel they have substantial grounds for objecting. It is a question of fact, easy to be ascertained, and not of mere "logic." There is no doubt as to the duty of a gardener to render his charge in the highest degree productive. That has nothing whatever to do with the matter at issue. As to your correspondent's "free" trade professions, I doubt if he would feel himself "free" if he were "fettered" by taxes that more favoured amateur traders ought to bear.

"A. E. H." contributes a very sensible letter on the same page (107). If it be correct, and I am not in a position to dispute the statement, that grain can be conveyed at as little, if not less, cost from New York to London as from Cheshire to London, an alteration is urgently needed, and such an anomaly we will hope will not escape the attention of the Royal Commission on Trade. Still, with all our disadvantages, your correspondent says American and English producers are "nearly equal," the balance presumably being in favour of the latter. Why, then, the collapse of British agriculture? I say, if it is anything but temporary, the fault lies in inferior culture. The importation of poultry and eggs is a puzzle, and the fact of £10,000 a day being sent from this country for the needed supply is no credit to British farmers.

"A WISHER FOR FAIR PLAY" writes like a farmer, and, farmer like, appears to fancy a gardener is out of his element in alluding to the ancient craft of husbandry. Of course "rents must fall and wages come down;" that is the farmers' remedy. Well, they have come down, in not a few instances quite low enough in my opinion. Will "A Wisher of Fair Play" say why the rents of labourers' cottages should not "come down," since wages have been reduced 20 per cent.? If it is right for those rents to be rigid, why should the rents of farms glide away to nothing? Let us have "fair play" all round if possible. Perhaps as time goes on your correspondent will find I have been "one year" in a farmhouse. I am in a position to say there is no work on a farm that I have not done, and if my eye and hand have not got feeble, I think I could drive a plough the "nearest way across a field" yet. As a farmer, your correspondent will know what that means. Then we are to give up growing Apples in this country because of the bad "climate." Was "Wisher," &c., at the International Apple Show at the Crystal Palace a few years ago, where the best American samples were staged with the English? Taking them bulk for bulk, the English would have realised more money than the American if both had been sold by auction "on the premises." It is selection and culture that win, not "climate" alone. The orchards of England are, as a rule, in a deplorable state and produce tons of trash. And Covent Garden is not the market for fruit grown a hundred miles north of King's Cross. There is too much sending to "Covent Garden." I do not believe in Covent Garden for northern produce, which should go further north still, even to St. Petersburg. There is as much reason in sending coals from Wales to Newcastle as sending Apples from Yorkshire to "Covent Garden." I am asked if I have ever known Wheat below 28s. a quarter. I have never known good Wheat so low as that, but I can remember when the average prices of farm produce all round were lower than they are now, even at Boston. By the way, I was once at Boston. It is years ago, and I daresay if your correspondent were to guess for a week what I was doing there he would not guess correctly. Shall I tell him? Yes, I will, just for the novelty of the thing. Don't laugh. I was sent for a good many miles to take the "bass" in a grand concert—basses are mostly rough—and if he has an old file of newspapers he will find my name in the report, but not in the form now appended.—A THINKER.

## THE TULIP TREE.

LIRIODENDRON TULIPIFERA is the name by which this is known in books and catalogues, but the Tulip Tree is the appellation by which it is best known to most people. We have three large specimens of it here and six smaller ones. The largest is 95 feet in height, bushy, and a noble tree. At present they are all leafless and unattractive, but in June and July, when richly clothed in their shining green artistically formed leaves, and thickly dotted with thousands of their curious Tulip-like blossoms, they outdistanced every tree in the garden in interest and beauty. When not in bloom the tree may well be classed amongst "beautiful-leaved" plants, but the flowers are very attractive. In form or outline they resemble huge Tulips, and the exterior is almost of the same shade as the foliage, but the interior is of a creamy colour and of curious formation, so much so, indeed, that they do not require the company of any other flower to increase the attractions of a hand or dish full.

The tree is hardy and will grow in any soil or situation. Some young ones planted seven years ago without any special preparation have now assumed large proportions, and I am sure if all who are interested in good trees would introduce one or more of these before this planting season comes to an end they would soon have cause to feel thoroughly satisfied with their work. Being deciduous, they ought to be planted before coming into leaf, and of the two sorts of trees—viz., standard and dwarf, I think the standard is the most handsome. In planting it is an advantage to use good soil where it can be conveniently obtained, and each tree should be firmly staked as soon as planted. In dealing with such a tree as this it

would be a pity to place it amongst other trees and shrubs, as it is in every way suitable to figure as an isolated specimen on the lawn.—J. MUIR, *Margam, S. Wales.*

### RENOVATING VINES.

VINE culture is an important subject, as the articles, letters, and contributions to your Journal testify, and this induces me to give my latest experience upon some matters connected with it.

I have been in trouble with my Vines, and perplexed as to the reason of the deficiency or failure in foliage and colour, but I am now convinced that in my case exhaustion of the soil, or, in other words, starvation, was the sole cause. I had a house of Mnscats which in 1884 were in such a deplorable condition that I was upon the point of grubbing them up and planting young Vines, when one of my friends recommended me before doing so to use some of Jensen's fish potash manure. I did so, applying a quarter of a pound to a peck of soil to the square yard, giving the border a good watering. To my satisfaction the result completely confirmed all that Ville, the French agriculturist, asserts as to the efficacy of a normal or complete manure. The Vines last year, 1885, were the picture of health, and finished a splendid crop of fruit, the borders at the present time being a complete network of roots.

I have also used this manure for kitchen garden crops with gratifying success. When I examined the analysis the reason is not far to seek, for the fish contains ammonia in the flesh, phosphate of lime in the bone, and with the potash salts forms a complete fertiliser. I would strongly recommend anyone who has Vines in an unsatisfactory condition to give Jensen's Norwegian fish manure a trial, it is very powerful, and in general work but little is required.—J. G., *Draycot Gardens.*

### CULTURE OF BROWALLIA ELATA.

THIS favourite perennial should be grown by everyone having a conservatory, greenhouse, or stove to embellish during the winter and spring months. If necessary it may be had in flower all the year by sowing a pinch of seed in February and again early in August; but it is as a winter and spring-flowering plant that it is most deserving of culture, because it is during those months that the plants, which are of branching habit, are most prized for decorative purposes. The blue Phlox-like flowers, which proceed freely from the tops of the side shoots, are then of the brightest hue, and contrast effectively when associated with flowering plants of light and bright shades of colour. A stock of this beautiful and very easily managed plant can readily be raised from seed sown in 4-inch pots previously crocked and filled to the rim with a light compost consisting of three parts of sandy loam and one of leaf mould. Cover the seeds lightly with some fine soil, then put the pots in heat and cover them with a square or two of glass and a little moss, which must be removed as soon as the seedlings appear through the soil. From this time the seedlings should be gradually inured to light and air to prevent them from making a weakly growth, and with this object in view the plants should be grown on shelves near the glass. A board resting on a few flower pots on bricks in an early Melon or Cucumber frame would be a most suitable place in which to grow the plants in their earlier stages, protecting them from the ravages of slugs by dusting a mixture of fresh soot and quicklime along the board on each side of the plants.

Three plants in a pot will be sufficient, and the superfluous ones should be pulled out before they become crowded, and be transplanted in 4-inch pots if necessary to increase the number of plants. The latter should have a small stick about 18 inches long put to each plant for support, and be kept well supplied with water at the roots, and damped overhead with tepid water on bright mornings and afternoons, as much with a view to promoting a healthy growth in the plants as to prevent the attacks of red spider. If larger plants are desired a portion of the stock should be shifted into 6 or 8-inch pots; and those in the 4-inch ones, which I find large enough for all ordinary purposes, should be top-dressed with a mixture of pulverised horse-droppings and loam when the plants attain a height of 10 or 12 inches. This will enable them to develop finer heads of flower than would otherwise be secured.—H. W. W.

### SOWING PEAS EARLY.

I SEE in the Journal, February 4th, page 84, your correspondent, "Kitchener," says he doubts very much if the Peas I have named, with the exception of one, would succeed if sown before the first week in April. If I did not sow the Peas named before the first week in April my chance of success at the Royal Horticultural Society's Show at South Kensington, varying from the 1st to the 14th July in each year, would be small. The dish of Wordsley Wonder Peas that I won first prize with last year on the 14th July at South Kensington was from seed sown the first week in January, also the dish of House's Perfect Marrow that I gained a similar prize with was sown at the same time, and they are both wrinkled Peas. I would also say to "Kitchener" and others, if your land be rich and well drained sow Peas, either wrinkled or round, as soon as possible in January

or February, and you will not miss having a crop more than once in ten years.

"Kitchener" makes a mistake when he says eight pints of the Peas that I have named would cost 5s. per pint or 40s. the collection, for the whole ten pints would cost 19s. 4½d., and I consider that taking the quality of the Peas the price is not so extravagant as "Kitchener" would lead us, your readers, to believe.

I was pleased to see the remarks of your correspondent, "Lathyrus," February 11th, page 109, as he practically bears me out in the remarks that I have made regarding early sowing.—HENRY MARRIOTT.

### NEW v. OLD VARIETIES.

MR. MOLYNEUX'S sound advice on page 84 tempts me to offer a few remarks on the above subject. It is not alone in Chrysanthemums that old varieties are superior to many new ones, but in vegetable and other seeds. When entering on my present charge my difficulty, like many other young men's, would have been the first seed order, but, fortunately for me, my father is a gardener, and his advice on marking the order sheet was, Leave the novelties alone. I can get Peas from 1s. to 1s. 6d. per quart that yield produce of good quality as long as Peas are obtainable, and I should not be studying my master's interest if I bought Peas at 5s. per quart that may prove worse on the dinner table.

I tried a new Beet last year, but it was not so good as Dell's Crimson, of which I get four times the seed for the money; this year Dell's only will be grown. I do not grow many varieties of anything. Brussels Sprouts are represented by Aigburth only, Cauliflowers by Early London and Veitch's Autumn Giant, Tomatoes by Hathaway's Excelsior, and Turnips by White Stone and Chirk Castle. I possess good varieties of Cabbage, Celery, Lettuce, and Onions, and save my own seed. Like Mr. Iggulden, I shall buy no more Melon seed. I have bought seed labelled Read's Scarlet Flesh that produced three kinds of fruit, none very good. For the future I shall grow only a seedling of my own. I would have enclosed my seed order for publication in the hope of helping some perplexed youngster, but it seems such a modest affair I am almost ashamed of it.—A. L. G.

### HIBISCUSES.

WHEREVER it is desired to increase the collection of flowering plants in the stove a few plants of the numerous forms of Hibiscus should be obtained. The flowers of most of the single varieties are somewhat fugitive, and in the case of *H. Rosa-sinensis* they are extremely so; but to compensate for their brief period of beauty they are produced successively for a considerable time. They are also welcome for their brilliant hues, as in most stoves there is too great a preponderance of foliage and insufficient brightly coloured flowers to render them attractive. The conservatory is commonly far more beautifully furnished in this respect, although the deficiency in the warmer structure is more due to want of selection than to an insufficiency of plants suitable for the purpose. Fine-foliage plants have had a large share of popular favour, but they are now losing their high position, and the demand for flowering plants is proportionately increasing. In consequence, any additions that can be named are welcome, and amongst these must be counted the Hibiscuses.

The genus is a large one, and comprises species of very diverse habit. We have groups of both hardy and stove annuals, then a group of hardy herbaceous perennials, including the deciduous shrub *H. syriacus*, which, with its many coloured varieties, is a common occupant of town gardens. A few also of shrubby habit, but evergreen, are obtained from Australia, and require a greenhouse temperature, while larger numbers are from the tropics in various parts of the world, and have to be grown in the stove. It is to the latter that reference is now specially made, and as their culture is simple it can be summed up in a few words. Most of them are free and quick growers, at least all those of the *H. Rosa-sinensis* section, and require an open compost of light turfy loam, leaf soil, and sand, in the proportion of two-thirds of the first to one-third of the two last named. Then if the plant requires any additional support, it can be afforded in the shape of liquid manure at the time of flowering. The pretty variegated *H. Cooperi* is too seldom seen in vigorous health, and it needs a lighter compost than that described for the other forms, substituting peat for the leaf soil and using sand freely. Very old plants of this are also liable to become what is termed "scrubby"—that is, producing rough bare stems with a few leaves at the points only, and it is then very unsatisfactory it is preferable to grow on a few young plants as stock to succeed the others. The same remarks apply to the flowering Hibiscuses of the *Rosa-sinensis* type, although by hard pruning these can be more readily furnished with fresh growth. All these are easily increased by cuttings inserted in sandy soil in heat. To insure the production of compact specimens the shoots of the young plants will need stopping several times until they are well branched and bushy. They flower in a small state, but it is not until specimens 2 or 3 feet in diameter are obtained that they are really seen in their best condition.

*Hibiscus Rosa-sinensis* is an old inhabitant of British gardens, for it was known to and cultivated by Miller in the last century, as early as 1731. The single form was that first grown, and though not quite so brilliant as some of the varieties that have been subsequently obtained, its flowers were of a fine rich red colour. One of the old writers—Rumphius—gave a full account of this and the double form, together with a figure of the latter, which he stated was more generally grown both in China and India than the single variety. He also remarks upon the fondness of

the inhabitants of India for red-coloured flowers and refers to a peculiar and very unæsthetic use to which the flowers are applied—namely, for blacking boots. They are rubbed on the leather, which is then polished with the hand. In this country we are content to employ them for floral decorations alone. Innumerable varieties have been raised or introduced differing in hue, from the most brilliant red to yellow flesh colour or nearly white, and the majority have received high-sounding names, such as “brilliantissima,” “magnifica,” &c., while of doubles we have red yellow, and striped varieties, all attractive and lasting longer than the singles. Collieri and Baptisti are two handsome named varieties of the double type, but several others can be found in nurserymen’s lists.

A pretty companion for the bright-coloured *H. Rosa-sinensis* varieties

most striking appearance, and attract great attention. Owing to the margin of the corolla being so deeply and irregularly divided, the flowers are most remarkable, and seem almost feathery in their lightness.

Many more could be named, such as the changeable *H. mutabilis*, the lilac *H. lilacinus*, the purple *H. phoeniceus*, and others, but those mentioned will suffice for ordinary collections.—L.

#### THE BEST MELONS.

UNDER this heading appeared an article in the Journal of the 4th inst. from a well known correspondent, but it seems to me difficult to tell which is the best of the many varieties there are at present in commerce.

FIG. 22.—HIBISCUS DENNISONI.

is *H. dennisoni* (fig. 22), distinct in foliage and flowers. The leaves have been compared to Ivy, and they have a rounded form suggestive of the variety known as the “Irish Ivy.” The flowers are large and funnel-shaped, of a creamy white colour, light and delicate, contrasting well with the red flowers of the species previously named. With ordinary attention in cultivation, such as that already advised, plants of neat compact habit can be had in pots of moderate size, and it flowers very freely when quite small.

As a beautiful curiosity *H. schizopetalus* ought to be widely grown; the drooping flowers with their orange scarlet deeply cut petals have a

In a catalogue before me now forty varieties are offered, and I will venture to say that there is not one gardener in fifty who has room or conveniences for growing half of these roots. Raising new Melons seems quite a hobby with some people, but I think while we have so many good varieties this business might be abandoned, as many that are raised and certificated are soon lost sight of. In the garden where I received my first eight years’ experience Melons were grown on a large scale, and for a mid-season crop a lean-to house 60-feet long was annually planted with about a dozen sorts, and we ripened between seventy and eighty fruits, yet out of that dozen, though all were good a few years ago, only

three or four varieties can be obtained now. I should like to see the number reduced to about a dozen, four of each, Scarlet, White, and Green-fleshed. I grow four varieties, and find these sufficient. Hero of Lockinge is not a favourite with me; it has a very thick skin, and consequently more waste, which is not the case with some other varieties equally as good.—FAIRPLAY.

### BELVEDERE HOUSE, WIMBLEDON.

To Surrey Chrysanthemum growers the residence of A. Schlusser, Esq., is well known, as the beautiful specimen Pompons annually produced by Mr. Lynes have gained considerable fame in the district. The garden is also noteworthy in another and more important respect—namely, that though Wimbledon abounds in well kept establishments this one merits a place amongst the best for all-round neatness and good practical work. It is unpretentious, but those who appreciate good gardening can see much to please them in the manner small details are executed.

The glass houses are not very numerous, but their occupants all show that they receive careful attention. One feature is the Roses in pots, of which a good number is grown, and they are now under cover in preparation for their early flowering. The plants are healthy and are breaking regularly, the buds looking strong and very promising. The plants are repotted every year into good loam, they are allowed plenty of root space, and are supplied as occasion demands with liquid manure. A good collection of varieties, both Teas and Noisettes, is grown, and a valuable supply of buds and blooms they yield for a considerable time. In a house where there are two old Fig trees the utility of Roses for flower-yielding is, however, especially well illustrated. The Fig trees, both Brown Turkey, are planted out in a border in the centre of the house, and at the ends are planted Maréchal Niel and Reine Marie Henriette, the Red Gloire de Dijon. These extend to the centre of the house, covering the lower part of the roof, and afford blooms by hundreds through the early summer. The effect is also pleasing, the fine clear yellow of the Maréchal Niel contrasting with the red or pinkish Reine Marie Henriette, and for all kinds of floral decorations they are highly esteemed. Everyone knows the value of Maréchal Niel, but its companion is not so frequently grown in houses. Mr. Lynes, however, speaks very highly of its qualities, and recommends it strongly for the purpose to which he applies it. This house, though of moderate size and slightly heated, is an extremely useful one, as the Figs yield enormous supplies of fine fruit that ripen well.

A handsome span-roofed house in two divisions, erected a year or so since, is now chiefly occupied with Orchids in one division and with Ferns, Crotons, and other stove plants in the other. The house is spacious, lofty, and light, well adapted for the culture of plants, as can be seen from the way these thrive. The Orchids especially are very healthy, and small plants obtained eighteen months or two years ago have made wonderful progress. An example of *Dendrobium Ainsworthii*, a particularly fine variety, had when received only three small pseudo-bulbs, and now has eighteen, the majority strong and bearing abundance of flower buds. *D. crassinode* has three stout pseudo-bulbs in a 6-inch basket, and bears a total of forty-four flowers large and richly coloured. *Laelia purpurata* is represented by some strong specimens and good varieties. Several good Cattleyas and other Orchids are also grown in this house, the white and orange-coloured *Dendrobium infundibulum* flowering well. In another house is suspended a specimen of *D. Wardianum*, with growths over 4 feet long, and which has borne flowers 6 inches in diameter. A small cool house is devoted to *Odontoglossums*, all of which look well, but the pretty *O. Sanderianum* is the only one in flower now, though *O. Rossi majus* and several others are fast advancing.

In other houses are plentiful stores of useful plants for table decoration and similar purposes, *Dracenas*, *Crotons*, *Aralias*, *Palms*, &c., of moderate size being chiefly employed in this way. *Pelargoniums* are numerous, many of the best varieties being included; *Azaleas* have a good space devoted to them. *Eucharises* and *Amaryllises* form other attractions, though, unfortunately, Mr. Lynes has had to contend with a troublesome pest, the so-called *Eucharis mite*. Soaking the bulbs in a strong solution of Fir tree oil or the Gishurst compound for twenty-four hours has been found to be an effectual remedy, for bulbs so treated are recovering their usual health and making strong growth. The Peaches and Nectarines are opening their flower buds well in the early house, but the weather has been very unfavourable to them.—V.

### SOME SINGLE ROSES AS DECORATIVE PLANTS.

[An article by Mr. T. W. Girdlestone in the "Rosarian's Year Book."]

SINGLE Dahlias! Single Chrysanthemums! And now (oh, ye florists) single Roses! Well, why not? Nothing is perfect in this world, and we must have regard to a general law of compensation in the selection of the meritorious. Single Roses are so fleeting?—true, the individual flowers are; but look how each shattered blossom is replaced by a score of others, until profusion stands declared to compensate the want of endurance. These singles are no good for cut flowers or exhibition?—so much the better for the garden, which will thus be all the more attractive to get and keep people out of the house, while the making of a permanent garden at all times attractive is of far more importance than the decoration of any tent for a few hours; and at the same time it must be remembered that Hybrid Perpetuals only last a day during July. And then, single Roses do not flower in the autumn?—apart from the fact that this is not in all cases true, no more do about half the so-called "Perpetuals," over which the singles have this advantage, that they are as gay in the autumn with hews as they were in the summer with flowers; some bearing fruits large and

deep-coloured, some small and brilliant, some in bunches as big as rowans. And then, again, how good-natured they are, making themselves at home in soils and situations and with a small amount of attention, that many double Roses would die rather than put up with, and at the same time scorning the notion of mildew and green fly and such-like fashionable complaints. But argument is always useless; for those who only grow what is in vogue, or whose horticultural love is circumscribed and centred in that showy Miss First Prize, will not grow anything that is not prescribed by their leaders of fashion, nor conducive to the winning of their mistress; while those whose large hearts (and gardens, since it must be admitted that for very small gardens the most vigorous of the single Roses are not well adapted) have room for all that is beautiful will need no persuasion.

It only remains, therefore, to enumerate the most beautiful and best adapted for general cultivation of those single Roses which I have grown in case others may possibly not have come across some of them, and to give the mockers something definite to mock at; since general mockery is too easy to be entertaining, and we are told that as much entertainment as possible ought to be obtained from every "single thing."

Of all the plants in the garden this year I think that which was individually the object of the greatest admiration for the longest time was a Rose, whose single flower is no larger than one's thumb-nail, namely *Rosa polyantha* (= *Luciae*), one of the Multiflora (II.). (The Roman numerals refer to the groups as arranged in Mr. Baker's Synopsis of Roses, recently published in the horticultural periodicals). This plant covers a split-larch fence 12 feet high and 18 feet wide, and would readily have covered twice that area, as it grows with great vigour; in fact, rather than waste time over any one-sided arrangement it has penetrated interstices of the saplings, and already clothes the fence on both sides. Although the individual flowers are so small their petals are of the purest white, set off by the close bright yellow stamens, and they are delightfully fragrant; whilst they are produced in such immense clusters as to make the tree appear literally snow-wreathed. Gratitude, if that be really the concise term for a keen sense of favours to come, ought to be an additional inducement to the cultivation of this charming plant, since from accidental crosses through the bees' agency of this Rose and various Tea-scented sorts in the Lyons Rose gardens, have sprung those pretty and truly ever-flowering miniature Roses, the Polyanthas of catalogues, such as *Mignonette*, *Ma Paquerette*, *Perle d'Or*, &c.

*R. Brunonii* (II.) is another very pretty Rose growing with great vigour and making a good climber, producing bunches of white flowers somewhat similar to *R. Moschata*, the single Musk Rose, but more ornamental.

*R. setigera* (II.) (= *rubifolia*—a name which Mr. Baker does well to discard, as it gets much confused with *rubrifolia*, a very different Rose) is the Prairie Rose of North America and the parent of the "Gem," "Queen," "Beauty," and several other apocryphal things "of the Prairie," and is worth growing if only for the beautiful autumn colouring of its foliage. For its leaves are like those of the Bramble, not only in appearance, but also in the varied tints they assume towards the end of the year. The British representative of this group (II.) *R. Repens* (= *arvensis*), is the most beautiful of all our native Roses, and, if it only came from Peru or Siberia instead of neighbouring commons and hedgerows, it would probably be grown and admired as it deserves to be. But in spite of its being "only a wild flower," it should be remembered that it probably helped to originate the Ayreshires, and a place should be found for it in the wild garden, where it can grow as it likes; not trained up anything, for it is one of the few creeping as opposed to climbing Roses, but left entirely alone, when it will soon make a great mound of graceful slender growths to be hidden in June under a canopy of pure white flowers.

(To be continued.)

### ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 9TH.

SCIENTIFIC COMMITTEE.—Dr. M. T. Masters in the chair.

*Geoglossum* (?).—Prof. Boulger exhibited a specimen for determination of the name.

*Camellias and the Frost*.—The Hon. and Rev. Boscawen exhibited sprays of plants grown in the open, and which had been subjected to 10° or more of frost, in which the second and third year's leaves were browned, but last year's were perfectly green and untouched. The same fact had been often before noticed at Lamorran, and at Pentilly—a much milder locality than the former. The cause was presumed to be the relatively lessened vitality of the older leaves, though normally they remain on from three to four years. Dr. Lowe alluded to an instance of a plant (a single-flowered kind) which had been much injured in transit, and was planted early in the summer. It threw out foliage which has stood all the frost of the present winter. Dr. Masters alluded to the fact that some young Lime trees transplanted last autumn, and which had shed their leaves, threw out fresh ones, which likewise had withstood the frost. Both these facts, therefore, would seem to corroborate the view that the vitality of the young foliage was so strong as to resist the effects of the late frost, to which the older leaves of two years had succumbed.

*Peach Wood Injured*.—Mr. Wilson exhibited a specimen of wood in which the dissolution had occurred between certain years' growths, similar to the so-called "shaky timber."

*Catantem tabulare*.—Mr. O'Brien exhibited a blossom of this flower, remarkable for its resemblance to the opened mouth of a snake, the two "antennae" resembling the fangs, while a thick tongue-like elevation occurred down the middle of the labellum.

*Phalenopsis Stuartiana*.—He exhibited a spray of this variety raised by Major Leady, to show the permanency of the peculiarity of the petals, commencing to assume the characters of the labellum in bearing a similar, though much reduced process on the centre, and by being more or less spotted instead of pure white, as in the original form.

*Aspidium falcatum*.—He showed fronds of this species, raised from spores of a sport, with a yellowish-green tint, and which had preserved this peculiarity. It was raised by Mr. Naylor of Roxeth.

*Euonymus japonicus with Cocco*.—Mr. MacLachlan exhibited leaves attacked by and covered with minute white cases of *Chionaspis Euonymi*.

It is said to prove very destructive at Montpellier and elsewhere in South Europe. The majority of cases were of males; very few of those of females being present amongst them.

*Haricot Attacked by Aleurodes.*—He also showed leaves of this plant badly attacked, and which was said to almost threaten the extinction of the Haricot abroad. We have one species on the Cabbage and one on Abutilons in England. The best remedy, he thought, would be Pyrethrum powder thrown on the under side of the leaf, which alone appeared to be attacked.

*Leaves and Dew.*—Mr. Smee read an interesting communication on some observations he had made during nineteen days upon the relative amount of dew deposited on leaves of different plants last summer. He observed the Quince, Syringa, Brussels Sprouts, Peach, Rose, Mulberry, Evening Primrose, and Dahlia, at seven in the evening and again at nine in the morning. It appeared that the leaves of the Quince and Mulberry are always the last to be coated with dew, and are never very wet at any time. Dahlias and Brussels Sprouts become coated with dew sooner than any other plants; while in the former, drops of dew hang from the points of every leaf. The leaves of the Peach, Rose, and Evening Primrose are never so wet as those of the Dahlia, but always had more moisture deposited on them than had those of the Quince and Mulberry. Mr. Smee also exhibited a table giving

Fig. 23.—The "Darlington" Glass Wall-cover.

the atmospheric conditions in his garden on the days of his observations. The plants were all similarly situated as to exposure, and were, as far as practicable, growing in close proximity to one another.

*Colletia bictoniensis* on *C. spinosa*.—Mr. Burbidge sent a specimen of this dimorphic species, now well known to exhibit this peculiarity. *C. bictoniensis* was first raised from seed of *C. spinosa* by Mr. Barnes of Bicton; the dimorphic sport first came from Italy twelve years ago, but has often occurred since then.

*Banksia australis* Raised from Seed.—Mr. Henslow exhibited the flowering spike from a plant raised from seed which had been kept twenty years. The plant was at present about 3 feet high.

*Plants Exhibited.*—Mr. T. Lynch brought five specimens of *Juncus acutus*. It was remarked that butterflies occasionally impale themselves on the sharp points of the erect leaves. He also showed sprays of the uncommon scarlet *Salvia boliviana*, *Acacia cyclops*, remarkable for the long scarlet funicle which is wrapped round the seed; this ultimately uncoils, and the seed is thereby suspended out of the legume. It was suggested that this might tend to mature the seed in the sun, or to attract birds. *Euphorbia punicea*, with leaves gradually passing into coloured bracts, as in *Poinsettia*, *Acacia platypleura*, with remarkably pale-coloured yellow flowers.

### THE "DARLINGTON" GLASS WALL-COVER.

GLAZED coverings for walls are so valuable for the protection of fruit blossom and accelerating the ripening of fruit, also for growing Tomatoes under, and sheltering Chrysanthemums in the autumn, that they might with advantage be much more extensively used than at present. The particular "cover" referred to is quite new, having been designed by the well-known firm of horticultural builders, Messrs. W. Richardson & Co., Darlington, "with the view," as they say in the prospectus, "to supplying a glass house for growing Peaches and other wall fruit at a price which brings it within the reach of all. The 'Darlington' wall cover is cheaper than anything of the kind that has ever been offered to the public, and, at the same time, thoroughly strong, well made, and durable. It is also portable in the fullest sense of the word, the entire front (which is composed of sashes), the ends and top glass being made so as to lift off with the greatest ease and rapidity. They can be as easily replaced, and every alternate light will then, if desired, slide (on runners) behind its neighbour, so as to give thorough ventilation. A

portable wood front, with cast-iron standards, as shown in the above section, can be supplied at the extra cost named in the price list, no brick-work whatever being required except the back wall. The 'Darlington' wall-covers are carefully put together at the works before being despatched, each part being numbered, so that they can be fixed at their destination without the least difficulty. Full instructions for doing this are sent with each length."

### CYCLAMENS AND PRIMULAS AT READING.

A RECENT visit to Messrs. Sutton & Sons' Portland Road Nurseries revealed a marvellous display of the above-named useful decorative flowers. This place is made a special "manufactory" of choice florists' flowers, and an inspection of these therefore is always highly interesting. "Specialities," which are grown in the best possible manner, so as to secure the finest development, so that the merits of all new claimants to honours are fairly tested. The Cyclamens form a beautiful display, the plants healthy and freely flowered. It is well known that the firm have given careful attention to these increasingly popular and beautiful plants so valuable at this period of the year, one of the objects aimed at being to secure a good habit in the plant in addition to finely formed flowers, and in this laudable endeavour they have admirably succeeded, as the plants under notice amply testified. The habit is dwarf and "stocky," setting off to additional advantage the tall furnished heads of bloom thrown up above the foliage. The plants are grown on the rapid system of cultivation, those in flower being about fifteen months old. It says much for the treatment that produces such grand results. It may prove of interest to put on record the names with brief descriptions of a few improved varieties noted, and the list may be well started with White Butterfly, aptly named, a snowy white flower, undoubtedly one of the purest white-flowered Cyclamens yet raised. It is compact in habit with beautifully marbled foliage; the flowers broad, rounded, not pointed as in some varieties, are produced freely, and are remarkable for great substance and good form. A sterling variety, Album, is a good pure white; the petals more pointed than in the preceding variety. Roseum album, white, with a red base. Phoenix, intense fiery crimson. Roseum, pretty shades of carmine and rose. Rubrum, a fine deep red flower. A pure purple-coloured Cyclamen has yet to be raised, but Messrs. Sutton are "on the way" to attaining this much-desired novelty.

Amongst the giganteum forms, a magnificent strain, with flowers of extraordinary size and great substance, leaves large and very beautifully marbled with silver grey, may be mentioned the following good sorts:—Roseum superbum, colour unique, a bright rosy pink. Album, flowers very large and pure white. Roseum album; the flowers of this variety are almost as large as those previously named, but differ in colour, the base being deep rose, and the upper part of the petals pure white. As showing the extraordinary floriferousness of these Cyclamens, it may be noted that one plant will produce, from the beginning to the end of its flowering, from 200 to 300 flowers, and they last three weeks in a cut state—valuable qualities to be turned to account by the decorative florist.

The Chinese Primroses alone make a beautiful display—a feast of flowers! A grandly grown collection was on view of Reading Blue. This is the deepest of the blue-flower Primulas yet introduced. It is compact in habit, with large flowers, which are produced in abundance and thrown well above the foliage. A suitable companion to this is to be found in the Double Blue, a useful flower, particularly for cut purposes. Pearl, a white variety with finely fringed flowers, habit good, flowers produced abundantly, standing in quite a pyramid above the healthy foliage, and rendering it very distinct. Ruby King, deep blood red, remarkably compact in habit. New Giant Lilac, a novel variety of exceedingly robust habit, and with large attractive lilac-coloured flowers; an acquisition. Amongst Fern-leaved varieties, a class valuable for table decoration on account of their beautiful foliage, we were especially struck with Gipsy Queen, the nearly white flowers being well shown up by the rich dark foliage. Snowdrift, pure white, a model in all that constitutes a good Primula; habit, foliage, and profusion of flowers being all that the most fastidious could desire. Rosy Queen, colour a delicate salmon-rose; habit compact; a beautiful variety, especially adapted for table work, some plants in 72 and 60-size pots being little pictures that would cause a pretty effect dotted here and there. It is surprising that such young plants should bear such heads of bloom, nor were they deficient in leafage.

How valuable, particularly at this dull season of the year, are the double-flowered varieties of Primulas, their rosettes of flowers coming in so useful for bouquets, sprays, and table decoration. The single-flowered varieties, though beautiful, are rather fugitive when used for the purposes named. How free, too, in the matter of flowering! Some we noticed 20 inches in diameter and the same in height covered with blooms. Some of the most striking amongst them may be noted. New Double Scarlet, the brightest double scarlet Primula yet seen, robust in habit, and very free flowering; its brilliant colour is seen to great advantage by artificial light, therefore is invaluable for table decoration. New Double Rose, beautiful soft salmon rose colour, flowers thrown well above the foliage; a charming variety. Amongst the double Messrs. Sutton have raised what are designated Special Hybrids. By carefully hybridising many of the finest varieties, a choice strain of double and semi-double flowers has been obtained, foremost amongst them being Double White, pure white, double and semi-double flowers, very useful for cutting. Red, brilliant

magenta red. Carmine, rich carmine. Lilac, a pleasing contrast to the other double-flowered varieties. Amongst Primulas not yet sent out may be mentioned a beautiful pink-flowered variety, as yet unnamed, but well worthy of this distinction, which it will undoubtedly get, after undergoing the necessary probation, all varieties put into commerce having to come up to certain standards of excellence. Another, having a perfect ring of pink colour to its beautifully Picotee-edged flowers, a novelty; and yet another good thing in the shape of a beautiful orange scarlet flower approaching magenta, its orange centre rendering it very conspicuous and striking. A dense Parsley-leaved variety was also very noticeable, its double lilac-coloured mottled flowers being quite an attraction, well set off by the peculiar bronze foliage. If for no other purpose, these Primulas appear to be well worth attention and cultivation for their characteristic foliage, which renders them very distinct.

In passing, we noticed some good Cinerarias and Calceolarias that will constitute important features later on. Next to attract attention were some finely ripened tubers of Begonias just twelve months old. These are a speciality at Reading, as also are the Gloxinias and Amaryllises, which are now, like the Begonias, in a resting stage, but from their present plump and sound appearance they give promise of a bountiful harvest of bloom in the future. We cannot refer in detail to the pits outside full of Picotees and Carnations, the useful showy hardy Primula japonica and other types, some of which we may hope will be seen at the forthcoming Primula Conference, Lobelia cardinalis, Anemones, Tritomas, the beautiful Schizostylis coccinea, Geums, herbaceous plants, &c., all at present in comfortable quarters, awaiting their removal to beds prepared for their annual reception.—B.

#### KITCHEN GARDEN.

**ONIONS.**—Autumn-sown plants which have been disturbed by the frost should have attention. When the surface of the ground is open and soft sprinkle a little soot all over the plants and then tread the soil round them firmly. This will induce them to make strong short new roots, and in a fortnight or three weeks they will be in excellent condition for transplanting. It is yet too early to think of sowing the main crop of spring Onions, but a small quantity of seed may be sown for early use. The Queen variety grows fast, and if sown now would have formed good bulbs by June. White Spanish is the next quickest. Select a sunny spot where the soil is light for the present sowing. We have tried to get exhibition "spring Onions" by sowing at this time or in January, but the young plants were so severely checked in March that we found early sowing in the open no advantage. Under glass, however, young plants may be brought on freely, and if a few old boxes are filled with rich soil and the seed sown thinly broadcast on the surface, capital plants may be secured for placing out about the first week in April. The seed will germinate in a temperature of 65°, and as the plants grow they should be gradually withdrawn from the heat until they are in a cold frame. We have to-day sown a dozen boxes full of Onion seed, the varieties being Giant Zittau, Cranston's Excelsior, and seed we had from a friend in Spain, selected from handsome bulbs 2½ lbs. in weight. There is nothing like plenty of sun for Onions.

**PARSNIPS.**—Where large roots of these are wanted by August or September the seed should be sown now. The Student is the finest in quality, but Carter's Maltese is much larger, and where fine roots are wanted for exhibition the latter should be sown. The soil for them should be 2 feet deep at least, and it should be very friable and free from large stones, clay, or rough manure. Soil which is heavy or too stiff for them may be lightened and made suitable by digging a quantity of sand or ashes into it. The rows must be from 20 inches to 2 feet apart, and the seed be sown very thinly, as ultimately the plants will be thinned to 1 foot apart. These distances apply more particularly to the production of large roots for exhibition, but where the Student is grown for kitchen use only 15 inches between the seed rows will be sufficient.

**LETTUCE.**—Where seed was sown in the autumn and the plants were dibbled in close together in a sheltered place in November they ought to have kept very well, and will now be healthy little plants. Each one of them can be lifted with a ball of soil attached to the roots and be replanted 10 inches apart in good soil and in a very sheltered position. We put our plants out along the bottom of a wall, and they invariably do well. A little seed of the Early Paris Market or some other early variety should be sown now. This, too, must be put in a warm corner, and in light sandy soil if possible. Lettuces in April and May are as much valued as at any other time in the whole year, and to secure a good supply then is deserving of a little attention at present.

**POTATOES.**—Those in frames and under glass in various positions are growing freely, and the secret of having the stems and leaves robust and the produce good and plentiful, is to grow them in the full light and admit fresh air to them on all favourable occasions. During frosty nights

it may be necessary to cover them with mats or straw, but this should never remain on in the morning later than is necessary, and although some might think they are forcing them by keeping the light close, when the sun is shining this only weakens them. Some early tubers may now be planted in the open ground. We always plant our first Potatoes out of doors along the bottom of a Plum and Peach wall. When the Potato growths are coming through the soil in March the trees are being protected with netting or something of this sort, and the Potatoes also benefit by this to such an extent that they require no other protection, and it is very gratifying to observe how well they succeed under these conditions. The sets are put in about 18 inches apart, and some good material in the form of old Mushroom bed manure, leaf soil, &c., is given them as for a first crop, and to secure the best results it is impossible to be too kind to them. Frame Potatoes are very well, but we never look on them as a profitable crop, and in quality they are not to be compared with those we dig from the border near the wall.

**RADISHES.**—Those sown some time ago will now be up and growing freely. When under glass they are very apt to run into top growth, and when the leaves are very crowded good roots are never formed. Thin sowing is a cure for this, but few sow so thinly as they might do, and crowding young plants in spring is a daily occurrence, the evils of which can only be averted or remedied by timely and liberal thinning of the young plants. In the case of frame Radishes this should be done as soon as the plants are large enough to handle, and by leaving them just clear of each other every one of them will form a useful root. Open air sowing may now be practised, but success can only be expected from seed sown in a warm place. Of late years we bring this sowing of Radishes on by placing four boards on their edge frame fashion on the open ground, sow inside these, and then put a glass light over them to rest on the boards. This forwards and protects the crop wonderfully, is cheap and profitable.

**SHALLOTS, GARLIC, &c.**—The bulbs of these should be planted out. They will succeed in very shallow soil if it is rich and light. The best of the bulbs which are left from last year should be used for planting. The Shallots may be put in rows, allowing 10 inches between the rows, and 6 inches from bulb to bulb. The Garlic should have a few inches more space between the roots. If the soil in which they are planted has been recently dug the surface will be quite friable, and each bulb may be pushed into the soil with the hand. The top of the bulb only should just be seen above the soil. Potato Onions require the same treatment, but as they grow larger and become large clusters it is well to keep the bulbs 1 foot apart each way. These Potato Onions are much grown by many small garden holders, and as they are hardly ever affected by the grub or disease they are very satisfactory.

**RHUBARB.**—Where roots of this are scarce and only a few large ones exist the stock may soon be increased by digging up the old roots and dividing them into several pieces. If planted again at once into deep rich soil each one will bear well in early summer. If possible the roots ought to have a fresh place to grow in, and high-class produce will only be produced in the richest soil.

**FORCING.**—As the days lengthen and Kidney Beans and other young vegetables gain strength, give them more water, and as they begin to show fruit use guano water as a stimulant. Sow successional crops of every vegetable which is passing.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Earliest House.*—Forcing owing to the continued sharp weather has still to be carried on by fire heat, and the fruit in consequence are later than usual. The trees, however, look well, and the time cannot be distant when we must have a change, and the fruit make rapid progress. In the meantime a steady course will be found the safest, maintaining a night temperature of 50° to 55°, and 60° to 65° by day artificially, and 5° to 10° more from sun heat, especially after closing, which will keep the trees in steady progress. Disbudding must be regulated by the growth. When the growth is strong the whole of the foreright shoots may be taken off at once, and some of the side shoots pinched back to form spurs on the extensions but not on shoots that will be removed after the fruit is gathered, always bearing in mind that the best break from the base must have room for extension and full exposure to light, and a shoot must be retained on a level with or above the fruit to attract the sap to it. Trees that have started weakly from overcropping in previous years, or are not very active at the roots, usually set freely, but to ease these no time should be lost in removing the least promising fruits from the under side of the trellises, and to help such trees supply weak liquid manure, and syringe the border, paths, and walls with clear liquid of the same character, which will soon cause an improvement in the colour of the foliage and strength of the growths. Syringe in the morning and early afternoon with water a few degrees warmer than the house, always, however, early enough to allow the foliage becoming dry before night. Ventilate a little at 60° and increase it with the rising temperature, avoiding cold draughts and sudden depressions of temperature. Examine inside borders, and give tepid water freely when necessary until it passes the drainage.

*Second House.*—Trees that were started early in the year will have set or be setting the fruit, for which fertilisation must be daily resorted to, and when the fruits are all set syringing will need to be resorted to, which will soon clear them of the remains of the flowers. The night temperature should be kept at 50°; 55° by day, and 5° to 10° rise from sun heat. Until the fruit is fairly swelling disbudding should be carefully

practised, and when commenced be followed up gradually. If there be a thick set of fruit gradually remove the smallest and worst placed.

**Third House.**—The house started early in this month will have the flowers well advanced, and should as a precautionary measure against aphides be fumigated, having the trees dry, and repeating it on alternate evenings. Cease syringing when the anthers show clear of the corollas, but maintain a genial condition of the atmosphere by damping available surfaces in the morning and afternoon. A temperature of 50° should be secured by day, and 40° to 45° at night will be sufficient for the present. Ventilate from 55°, allowing an advance to 60° or 65° from sun heat, with a free circulation of air. If there be any doubt as to the moisture of the inside borders make an examination, and if necessary give a thorough soaking with tepid water. If there is a great show of blossom rub off those at the back or under side of the shoots.

**Late Houses.**—Keep these well ventilated by night and day, except when frost prevails, and when the days are bright some shading over the roof lights will prevent the temperature rising so as to excite the buds and get the borders properly moistened before the buds begin swelling, or many of them will fall.

**MELONS.**—Where the weather still continues severe a night temperature of 60° to 65°, and day of 70° to 75° from fire heat will be suitable, rising to 80° or 85° with sun. Ventilate a little at 75° and close at 85°, rising to 90° with plenty of moisture. The plants that were shifted into 6-inch pots will now be ready for planting out in the ridges or hillocks in the Melon house for trellis training. Train with a clear stem to the trellis, rubbing off the side shoots as they show, and allow the leading shoots to advance two-thirds the distance up the trellis before stopping, also rub off every alternate lateral on opposite sides of the principal shoots. The laterals will show fruit at the second or third joint, or if no fruit show stop at the second joint. The soil should be moist when the plants are turned out and the soil pressed firmly around each stem, and keep the base of the plant a little higher than the surrounding level, so that the water may drain from not to the stem, for if the plant be low at the collar it is liable to become too damp and cause canker. Keep the bottom heat steady at 80°. Water carefully and always at a little distance from the stem. Maintain a genial condition of the atmosphere by damping in the morning and afternoon, also before dark if sharp firing is necessitated.

**CUCUMBERS.**—Endeavour to insure a steady progress in the plants, as nothing is gained by undue excitement at any time, especially when the weather is adverse to growth. Let the ventilating with stopping, tying, and regulating the growths be attended to regularly. Keep the evaporating troughs filled with liquid manure, the ammonia arising from which is invigorating to the plants and detrimental to insects.

**FIGS.**—*Earliest Trees in Pots.*—In a steady bottom heat of 70° to 75° the roots will now be very active and the trees have a number of fully developed leaves, which, when exposed to the full influence of light, need particular attention in the watering, as dryness at the roots will prove fatal to the most forward fruit. The pots being full of roots, hoops made of lead or zinc 4 inches deep should be placed inside the rims and rich surface dressings given as the roots occupy it, not giving it all at once, but little and often, and liquid manure in a weak tepid state in sufficient quantity to pass through to the drainage. The atmosphere must be kept in a genial condition by syringing twice a day when the weather is fine, and by damping the surface of the bed, walls, and paths when dull. Keep the night temperature at 60°, falling 5° on cold nights, 60° to 65° by day artificially on cold days, and 10° to 15° rise with gleams of sun. Ventilate at 70°, keep with sun heat through the day at 75° to 80°, and close early, so as to run the temperature to 85°. Attend to stopping and tying as growth advances, and guard against overcrowding as one of the greatest evils, for Figs to have flavour and colour must have full exposure to light and a free circulation of air, to effect which the growths must be thin and evenly placed.

**Early-forced Planted-out Trees.**—Those started early in January will soon require disbudding and stopping, but where trellis room admits the leading shoots should be allowed to extend to the extremity without stopping, mulch the borders with rich compost as the roots rise to the surface, and water freely with tepid liquid manure, encouraging roots by keeping the surface of the border moist.

**Late Houses.**—Pruning and cleansing the trees must now be completed and the houses closed by the end of the month. In late houses the growths should be kept thin, so that the young growths may be firm, short-jointed, and with judicious management well matured, otherwise satisfactory crops can hardly be expected.

#### PLANT HOUSES.

**Azaleas.**—Varieties of *A. indica* as they cease flowering should be placed in a temperature of 50° to 55°. When these plants have been forced into bloom by gentle heat, they are seriously checked if placed in cold quarters after they have flowered; but if placed direct in some structure where the temperature advised can be maintained, they continue making their growth. It is much better to assist plants to make their growth early in the season by gentle heat than to force them unduly. These plants should be syringed twice daily, and the atmosphere of the house in which they are arranged kept moderately moist. Under these conditions the roots of the plants will soon be in full activity, and when in this stage those that require repotting should be done. Employ clean well-drained pots, and the new soil, which must consist of peat and coarse sand, should be pressed firmly into the pots. In fact, it must be made a little firmer than

the old ball, or, when water is applied it will pass through the new soil and leave the old ball dry. The old ball as well as the new soil at potting time must be in an intermediate state of moisture. Freely syringe the plants after potting, so that water can be withheld from the roots as long as possible. This gives them ample time to recover from injuries received in the operation. In potting, the old ball should not be disturbed further than the removal of the drainage from the base. All that it may be necessary to keep in small pots may have a little Standen's manure applied to the surface, at intervals of about a month. Straggling shoots may be pruned back so as to keep the heads of the plants shapely and within due bounds. Watch for thrips, and if they appear destroy them with a weak solution of tobacco water.

**Epacris.**—As the flowers fade prune these close back and place them in a similar temperature to that in which they have been while flowering. If these are syringed twice daily they will soon break into growth. For this purpose these plants enjoy gentle heat, but as soon as they have made 1 or 2 inches of growth, gradually harden them to cooler treatment until they can be grown under cool conditions. The roots of these plants are generally active by the time 2 inches of growth have been made, and in this stage they may be repotted if they require it, using the same soil as advised for Azaleas; observe the same conditions as regards potting throughout. Artificial manure is also beneficial to those plants that do not need repotting.

**Heaths.**—Such varieties as *E. gracilis*, *E. hyemalis*, and others of a soft-wooded nature that were cut back late last year and failed to flower will, if they have been properly treated, be in good condition for transferring into larger pots. If these plants have now young growing shoots upon them about 2 inches in length, they will make beautiful specimens for flowering early in autumn. Press the compost of soil, peat, and sand firmly into the pots. If the plants are crowded with shoots they may be tied out or thinned; if the latter, those left will attain a greater size, and a few well-flowered shoots on each plant are more effective than those with a greater number of smaller shoots. Young stock in 3 and 4-inch pots with five or six young growing shoots upon them should be placed at once into 5 and 6-inch pots, according to their size and strength. These, if well cared for, will by autumn be equal to those plants grown by the trade in the neighbourhood of London. Grow these plants in frames where frost can be excluded by means of hot-water pipes or by matting during bad weather. The frames may be kept moderately close and the plants carefully watered until they have commenced rooting into the new soil. Ventilate freely afterwards to ensure a sturdy compact growth. Plants that flowered and have been cut back should be pushed into growth as quickly as possible, or they will fail to make their growth and ripen it sufficiently to flower well in autumn and winter. For this purpose the plants may be kept in a temperature of 45° to 55° by night, and syringed once or twice daily according to the state of the weather.

**Hardwooded Heaths.**—All that require potting should be done at once, so that they will become partially established in their pots before the sun has too much power. Select some of the best peat for these, broken up with the hand and used in a moderately rough state; in addition to a liberal dash of coarse sand a little charcoal may be used with the peat. The soil should be pressed firmly into the pots, and the plants stood upon some moisture-holding material in the house in which they are grown. The ventilators may be kept closer for about a fortnight after potting, and the pots and stage being liberally syringed, so that water can be withheld from the roots as long as possible. After potting has been completed push on staking and tying as rapidly as possible. No more stakes than sufficient to maintain the plants steady should be used. If the plants are tied with green thread very few stakes will be needed. The only tying that young stock needs is to bring down the strongest shoots towards the rim of the pots, so that the smaller and weaker ones will have a chance of gaining strength. When growth commences strong shoots that take the lead should occasionally be pinched. Young healthy plants when potted may be placed into pots 2 inches larger than those in which they are growing.

## THE BEE-KEEPER.

#### ABOUT BEES.

In the spring of last year I gave your readers an account of my experience in bee-keeping. I had twelve stocks then, apparently flourishing, and as I had a swarm on the 1st of April it seemed likely that we should retrieve the disasters of the previous season. By May, however, two stocks and the swarm were lost, so I began the season with ten, all in Neighbour's ten-bar-frame hive, No. 99 of catalogue.

I set out with the intention of succeeding if possible, and was equally resolved to state my experience as a guide to other amateurs. I fed the bees with flour cake and sugar candy, and have one opinion upon them both—viz., they may serve to keep bees alive, but need something to moisten them, and that bees cannot get without fetching it, which causes them to fly out in the cold air, get chilled, and die; whereas if the food were

supplied in a liquid form it would be at once available as food or store. The swarm that issued on April 1st was fed with syrup. The bees seemed to thrive, but I noticed a few days after they became uneasy, running in and out of the hive, and along the flight board. Clearly the queen was lost. The bees were very busy, however, formed comb along five bars, and resisted fiercely every effort at examination. I resolved to await the issue. Food ceased to be taken down, the bees left the hive, and I found no less than three royal cells in the comb they had made, and a number of drone as well as worker cells. What did this mean? That I had not secured the queen in hiving, she had died or been lost early, hence the effort to raise another with drones for the purpose of continuance of the race. One hive, though it had plenty of bees when I introduced the flour cake and candy, they all died, clear proof that they had stood a long siege, and had cast out the slain from day to day. Another hive, with bees taken from a neighbour in the previous autumn, also died, their heads all stuck in the cells, and so perished of cold one frosty night in April. They had plenty of honey in store, having been placed in a hive, the bees of which had succumbed to Ligurians in August twelve months before. This stock had lost its queen, as the bees were very irritable, and guarded the entrance with remarkable tenacity.

This was a poor beginning of the season 1885. The bees commenced swarming the first week in June, a galvanised bucket I used to get them into the hive with was filled to overflowing, and I had four such. I supered the four, and had four twenty-one sections of 2 lbs. each, filled with honey. I had other swarms, and second and third swarms at intervals up to the middle of July, which it was said would come to nothing, but I had an idea, derived from Mr. Pettigrew, that second swarms were as good as the first the year following their existence as a separate colony. Why should a second swarm be good for nothing? The queen is young, and if by judicious care in feeding we get sufficient bees for warmth so as to winter safely, I cannot see why it should not do well. Of course, if feeding is not intended, then I doubt not it will be worth little, if anything.

Altogether I had nine swarms, eight natural and one driven, I think is queenless, but it took food well in autumn, yet now shows a restlessness and activity which I do not like to see early in February. It has, however, plenty of bees, but I shall not make an examination until the weather gets warmer, nor feed before the middle of March. I tried to make another, and failed, and having two hives that did not swarm—only one that gave the swarm on the 1st April—I had nine swarms out of seven hives, and except the driven one all is well with them. They are very quiet, and the weight says they have store on hand in plenty. The Crocuses, however, are showing colour, and if the weather prove genial we may soon hear the bees' glad hum.

I wish to return to the swarm that issued on the 1st April. The stock was strong it issued from, and the old queen was deposed to make room for the new one. It is likely, food being scarce, that the emigration was insisted upon by the workers, and they drove her out. She was not in the cluster when hived, for I saw her majesty on the ground, and she took wing and rose to the pole on which the bees had clustered, and I thought I secured her at the second attempt at getting them into the hive, if not they would have left the hive and returned to the parent stock. They did not, however, but set to work and formed the comb with royal cells as before described. The old stock giving the swarm on the 1st of April did not swarm again, which might be due to my having supered it, and which the bees filled with honey.

Two swarms one day issued together and joined, and as they were first swarms I had four (rather five, as I shall show presently) stocks that gave no increase whatever, and really only had five that were profitable as regards honey—*i.e.*, for first swarms and one stock, or that from which the swarm issued on the 1st April. Six gave nine swarms—eight natural and one artificial. Though I supered the two that made no effort at swarming, no honey was stored therein. They neither swarmed nor stored honey in the supers. The queens were not prolific. I do not think so. One was a taken-up stock of the previous autumn put in a hive filled with store, and defunct through over-swarming and driving; the other was a late swarm put in a hive also containing plenty of store, everything ready to hand. I had swarms later that were put in empty hives, and there swarmed. I had read somewhere that these hives were the kind to put bees into if you had them, as the comb, to say nothing of the honey, would give the new comers a start. It seemed reasonable, but I do not consider it is, for the bees in swarming are gorged

with honey, and the first thing they do is to disgorge and form comb. The bees do not do well in such hives, and as regards swarms are, I think, best left alone, giving only comb formation, feeding and leaving the bees to form their own nest. It answers in autumn for taken-up bees, but even these are placed at a disadvantage when in hives where the bees have died out through loss of queen or robbing, especially the former, for the queen being lost the bees not only keep on storing honey, but pollen, or bee-bread; the cells that would have contained brood, had the queen lived, are crammed with this grub food in anticipation of a mother being reared, no doubt, and it hardens, giving the bees a great amount of labour in clearing it out in spring to make room for brood. They carry it out in pellets nearly as large as themselves, which must entail much labour, and interfere with the economy of the colony. I only tried one attempt at brood-spreading, it was the first, and for some time to come will be the last. It appears to be the best way to secure foul brood.

When the extractors—there was a trader that practised it with over thirty stocks within half a mile—commenced extracting, I kept a sharp look out with scouts to inform me of the doings of the enemy, and within twenty-four hours the Ligurians and half-breeds put in appearance and took a close scrutiny of every hive. Some fraternised with the blacks and lived on apparently good terms until autumn, when they disappeared. There was no robbing, I kept them on a war footing—*viz.*, strong, and narrowed the entrances in anticipation of an attack, and it certainly rendered them safe, as the assailants soon were seen running with outstretched wing along the ground away from the hives. It was tried again at the second extraction—*i.e.*, the robbing by the Ligurians and cross-breeds, the Carniolians, though scouting, did not attack, and proved a failure both as to robbing and fraternising. The next news I heard were that the trader was going to move his bees, and now they are gone. It is said that it does not pay, I presume on the extracting principle, but the chief reason, I think, was the extracting caused the bees to sting everybody for some distance around, therefore were a nuisance. If the bees did not pay in honey there was the sale of swarms or stocks, and hives were no inconsiderable manufacture; trade must have been slack if the bees did not pay in one shape or other. But I feel certain that feeding with syrup and extracting it, it may be along with pure nectar, is not the way to make anything pay. I do not think syrup can be converted into honey even by bees, and it is this that has brought down the price to 6d. per lb., and tells so disastrously against the keeper of bees upon honourable principles—*i.e.*, selling honey, not syrup. Syrup costs about 1½d. per lb., and to get 6d. for it after the trouble of boiling, feeding and extracting, must leave a profit of 200 per cent. This is bee-farming with a vengeance. The farmer and cottager who have pure honey cannot compete against such a system, and then people wonder why they don't keep bees. Make sure of a market for pure honey only, and then these, the farmer and cottager, who should be the most interested and benefited, will hold their own to the mutual benefit of themselves and the public.—G. ABBEY.

(To be continued.)

#### THE COTTAGER'S STRAW SKEP—HOW TO GET SECTION HONEY FROM.

ALTHOUGH I have been an interested reader of your articles on bee-keeping for some years, and have become one of the fraternity in a small way, I have never till now taken up my pen on the subject. After reading "A Hallamshire Bee-keeper's" article on the "Dark Side of Bee-keeping," I am afraid the latter gentleman will not think me particularly happy in heading my first letter "The Cottager's Straw Skep." Your correspondent tells your readers that the cottager's straw skep system was perfected hundreds of years ago, and he will naturally wonder what new thing can be written about it. Well, I do not suppose anything new will come of my scribbling, but old things are often acceptable to new readers, and if our worthy Editors think these notes of any service to these, the old hands will please pass them over. To begin with, I am not going to enter into any controversy with expert bee-keepers on the merits or demerits of any particular system, but I hope I may be pardoned if I take exception to the perfection of a system of management the "cheapness and simplicity" of which is summed up in "hiving the swarms and brimstoning those not wanted for stocks." I hope there are many hundreds of cottagers now to be found throughout this country who would be sorry to resort to the brimstone pit, and who work their straw skeps on much more intelligent principles than they did hundreds of years ago.

"Felix" has this week urged the necessity of every bee-keeper, who wants to get the best price for comb honey, turning his special attention to sections. There is no doubt about the soundness of his advice. The old supers or "caps" are scarcely saleable when put in the market along with honey in sections, and cottagers have found that out to their cost

during last season. I hope it may not be labour lost if I can draw the attention of those cottagers, or any who have straw skeps worked on the old plan, and try to show them how they can with little expense get sections from their old hives and so increase its value. But as the bee-keeping column is limited, perhaps it will be most acceptable to our Editors in small supplies, so having written this much I will defer entering into the subject till another week.—A COTTAGE BEE-KEEPER.

### DIVIDING BOARDS.

I THANK you kindly for answering my last query regarding reversible frames. I am pleased to say this is the most simple of any plan I have seen, unless it be with the compound frame hive explained by "A Lanarkshire Bee-keeper" which is capable of more diversity of working than any other hive, and more in accordance with the nature of the bees and well adapted for transferring the honey from body frames to supers without reversing, by simply changing the position of the combs. But my object in writing at present is not to discuss the special merits of any hive, but to get further information as to facts. In the *British Bee Journal* for January 14th (page 19), Mr. F. Lyon, in answer to a correspondent, says, "When bar-frame hives were originally used it was the practice to winter bees on all the combs. The division boards were then called 'dummies,' and the only use made of them was to remove them to give lateral space for the extraction of the frames without rolling the bees between the combs, &c." He then goes on to show the advantage of the close dividing board over the so-called "dummy." I know the feeling that exists regarding the invention of certain bee appliances and the pirating of others' ideas. I have also observed the invention of close-fitting dividing boards claimed by different parties. I have in use a hive which cannot be less than thirty years old, which has a close-fitting dividing board of Scotch make; and although I am an Englishman, and would gladly give the palm of victory to England, still I am inclined to think from the evidence I am in possession of that Mr. F. Lyon is wrong. The close-fitting dividing board is a Scotch invention, and was in use long before the "dummy," but will be glad to hear what your other correspondents have to say in the matter and establish the truth, all the more necessary seeing that so many ideas were given in this *Journal* first and pirated in the *British Bee Journal*.

I also observe a dispute in the same *Journal* about the priority of the "Benthall" crate. Crates similar to these, with the addition of boards for top and bottom for convenience for marketing, were made in Scotland in hundreds some six years ago. Mr. A. Cameron, Blairathol, is supposed to be the inventor.—J. H.

### TRADE CATALOGUES RECEIVED.

Thomas S. Ware, Tottenham, London.—*Illustrated Catalogue of Choice Hardy Perennials, Catalogue of Hardy Climbing and Trailing Plants, List of Chrysanthemums, and Catalogue of Hardy Florists' Flowers.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (N.).—We think the price of the pamphlet you name is 6d., but why not send a postcard to the author, whose address you have?

White Cineraria (F. G.).—The variety is no doubt effective, but not new. Messrs. Carter & Co. sent us several white Cineraria flowers last year, one of them, so far as we can remember, identical with your own.

Odontoglossum cirrhosum with "branching spikes" (B. P.).—It is usual for strong plants to produce "branching spikes," as they are commonly termed, but the correct title is panicle. At the last meeting of the Royal Horticultural Society a panicle was shown like that you describe, but not so large. Your plants must be in capital condition.

Soil for Roses (Omega).—We do not consider that lumps of clay mixed with soil are of much benefit to Roses or anything else. If you can dry some clay in a shed so that it can be pounded into a rough powder, and add one barrowful to five or six of the turf, you will have an excellent medium

for Roses, and healthy plants and fine blooms may be had with the aid of rich top-dressings and liquid manure.

Soil for Ferns (*Filices*).—The soil marked No. 1 would grow Ferns admirably, potting firmly and giving clear soot water as liquid manure when the pots become filled with roots, and you do not wish to place the plants in larger. With a supply of this we should certainly not purchase the more costly kinds. By adding powdered clay, or any strong soil you can get, it can be made heavy enough for many other plants, but you do not say what the choice plants are that you desire to grow.

Climbers for Roof (C. C.).—You appear to want what is not very easy to find. Roses thinly trained would not shade the roof to any great extent, and their blooms would be useful. The foliage can be kept clean by lightly fumigating the house before any insects appear. If you wait for them with the object of saving tobacco paper you will lose much more than you will gain. It is easy to err in covering a roof when flowering plants are arranged on the stages below. Strong-growing Fuchsias, planted out and trained and pruned like Vines, have a beautiful effect, but they are liable to the attacks of aphids and thrips. Timely fumigating is a preventive of both.

Striking Cuttings in the Tropics (*Cinchona*).—It is not necessary to insert your letter, as it might not elicit a reply from general readers. The ground itself in the tropics affords sufficient "bottom heat" for striking cuttings, if the right time be chosen for inserting them; and if kept moist, close, and shaded, under a handlight or glazed case, so that evaporation is arrested, and the leaves remain fresh, roots will be emitted the same as they would be in a hotbed at home.

Figs Falling (*A Kentish Subscriber*).—Figs that form in autumn, and are now as large as small nuts, are almost certain to fall in the spring or early summer. It is a good plan to remove these, and others that are less than the smallest peas may be expected to ripen, assuming surface roots are plentiful and adequately supported with water, and also gross growths are prevented by pinching that might otherwise attract the sap from the fruit. You say the trees have been "root-pruned occasionally," but that does not indicate their condition, and if they grow luxuriantly root-prune them again and fill in the trench with loam and a sixth part of calcareous matter, such as lime rubbish, pressing it down very firmly with a wooden rammer. Your object should be to induce short-jointed sturdy growth that will be matured in the autumn, and the fruit may then be expected to ripen.

Seedling Zonal Pelargoniums (*Amateur*).—If your plants are in separate pots we should neither repot them nor cut them down, but allow them to flower so as to test the merits of the varieties, then increase those only that are worthy of preservation; some of them may possibly be of little worth. If crowded in a box you might take off the tops, insert each in a separate small pot of sandy soil, in which they would strike in a temperature of 60° and upwards, and soon flower. If you do this the original plants might be planted out in the open border in due time, and there flower. It is as a rule the best for amateurs to grow named varieties, seedlings occupying much space, flowering sparsely, and a number of them not worth perpetuating; still, apart from producing a display, a certain amount of interest attaches to raising seedlings, and florists are satisfied if they get one superior variety out of fifty plants.

Improving Vine Border (J. C., Somerset).—If you extend the border under the glass you will find a difference in your tennis lawn. We think you can improve the Vines without disturbing the lawn, though the border is narrow. Take off the soil till you bare several of the main roots, but keep them with any smaller roots moist. Notch the large roots at intervals of 2 feet, cutting straight down almost to the centre, then with upward cuts—that is, the edge of the knife facing the house, take out wedges, all to be finished smooth and clean. Mix some sandy loam, leaf mould, and manure sufficiently decayed and dried to be rubbed through a three-quarter-inch-meshed sieve, and wood ashes in equal parts, with which surround and cover the roots 2 inches deep; then spread on 4 inches of turfy loam, placing on this a covering of manure for keeping all moist. Fresh roots will then form, and during the summer you can give liquid manure or a top-dressing of some approved fertiliser, one being approvingly mentioned in another column by a good gardener, and may be worthy of your attention. We have seen Vines greatly improved in a smaller border than yours by the practice advised.

Making Bone Manure (W. B.).—We extract the following recipe from the "Gardeners' Year Book" on making superphosphate of lime:—"Place 5 cwt. (or twelve bushels) of bone on an earthen floor, surrounded by a rim of ashes; pour on as much water as the bones will suck up, and then pour on 2 cwt. of sulphuric acid; it will boil somewhat violently for a while; when this has subsided it will get tolerably solid, and the ashes and all may be shovelled up together, and will be fit for use in a day or two." Another mode of dissolving bones is given in the same work which we cite:—"Take a large watertight hogshead and cover the bottom with about 6 inches deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full, placing a good thickness of ashes on the top. Leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshead, the bones will crumble to powder under a slight pressure, and form one of the most valuable manures ready for immediate use." The manurial value of bones consists in the great quantity of phosphate of lime they contain.

Newly Planted Vines and Roses (*Old Ebor*).—You had better not allow the canes to bear a "few bunches" this year, notwithstanding the designation "Fruiting Vines." They would bear fruit, no doubt, but might be so exhausted as to be practically ruined. Your object should be to encourage the growth of strong canes this year, and to effect this you will in all probability act wisely by rubbing off several of the buds from the top downwards, so as to concentrate the root force and sap on a growth starting from the base of the rafter, in fact the lower the better, provided you select a bold bud in a light position. As you give no particulars as to length and strength we cannot give a more definite reply. If the Roses have been dug from the open ground, shorten them to good buds from a foot to 18 inches

from the soil; if they have been grown in pots and planted without any material disturbance of the roots the shoots may be cut to about half their length.

**Amaryllis Belladonna (St. Edmunds).**—You could not very well have made a greater mistake than keeping the bulbs in paper bags till the present time. You had better plant them in gritty soil 5 or 6 inches deep, close to a wall facing the south, and let them remain there permanently. If you wish to flower this Amaryllis in pots procure some strong bulbs in summer, pot them in sandy loam, and they will soon throw up flower spikes. They must be placed on a shelf near the glass in a warm greenhouse, afterwards to make good foliage, and when the foliage dies down the pots may be stood on a base impervious to worms, near a wall facing the south till September, then remove some of the old soil, add fresh, and take them in for flowering. We find them succeed and flower better planted out as suggested than in pots, but strong fresh bulbs flower very well. You ought to have potted or planted your bulbs in August or early September.

**Encharises (T. B.).**—Your plants appear to be infested with the destructive mite that appears to be spreading very rapidly, and unless it is destroyed the plants cannot flourish. As you are a new subscriber you probably did not see what was published a few weeks ago on well washing the bulbs in a solution of softsoap and petroleum, 2 ozs. of softsoap with a little soda being dissolved in a gallon of boiling water, and stirring in very briskly while hot a small wineglassful of common petroleum, applying this as hot as the hand can be borne in it, rubbing it into every crevice with the aid of a soft brush. That has answered in the case of some infested bulbs, another cultivator having found a similar mixture of Gishurst compound and Fir tree oil efficacious, except when the insects eat quite into the bulbs. In that state they are beyond cure, and should be burned. Place them in rather small well-drained pots in turfy loam, adding sand and crushed charcoal to keep it sweet and porous, placing some of the latter in contact with the bulbs. Plunge the pots in a bottom heat of 80° to 85°, if convenient in a stove or pit having a night temperature of 65°, applying water cautiously and judiciously. When the plants are established they require copious supplies of water when flower stems are visible, liquid manure to support good foliage, and when this is fully developed a gradual reduction of water and a rest of six weeks or so. Then, when placed in heat, they throw up another series of spikes. Good plants well managed flower freely three times in twelve months.

**Sheep's Nose Apple (Sir Henry Allsopp).**—The specimens you have sent are of this variety, which is described as follows in the new edition of the "Fruit Manual":—Fruit, medium sized, 2½ inches wide and the same high; distinctly angular, broad at the base and tapering to two-thirds of its height, where it forms a contracted waist, and thence it narrows to the crown, where it terminates in five prominent knobs. Skin, bright crimson, striped with broken stripes of rich yellow, except where it is shaded, and there it is either yellow or marked with faint streaks. Eye, closed, with long erect segments, set in a very angular and plaited basin. Stamens, marginal; tube, long conical. Stalk, a quarter of an inch long, inserted in a wide and furrowed cavity. Flesh, tender, juicy, sweet, and with a mild acidity. Cells, ovate; abaxile. A Somersetshire cider Apple, and also good for cooking; in use during October and November. It is a very handsome-looking Apple, and of remarkable shape. Fruit often keeps till this season of the year.

**Starting Vines (F. J.).**—You may start the Vines now; in fact, we gather from your letter that they are starting, and their growth must be steadily maintained. It is not too early for them, but if you have no frames into which you can remove the bedding plants by-and-by they will become drawn and tender by the heat to which they will be subjected. Fire must be employed for the Vines in accordance with the weather and the condition of their growth. At present, and until the growths are half an inch long, a minimum night temperature of 50° will suffice, or say 55° at about 9 o'clock at night, as there may be a fall of 5° before morning. When leaves commence unfolding the minimum night temperature may be raised to 55°, increasing to 60° when the leaves are as large as your hand and the bunches advancing, and when flowering the temperature may be 65° or thereabouts. These are all night temperatures. When there is no sun whatever in the daytime let the temperature be raised from the pipes 5° or 6°, not more; but with sun it may be quite 15° above the night temperature respectively. Do not employ fire when you can obtain sun heat, this being by far the better and cheaper. Close early in the afternoons, syringing the Vines till they are fairly started, also damping the house on bright days; by early closing we mean so as to retain the maximum sun heat as long as possible; but do not allow the temperature to fall to the night figures before the fire is started, as it will certainly fall lower in spite of vigorous efforts to prevent it. The pipes should be warmed in the afternoon to meet the declining temperature, the weather being the guide as to the time and extent of the fire heat to afford. But do not "play with fire" and have your house warmer at night than in the day, or you will fail in your object. A little air should be admitted at the top of the house as soon as the temperature rises 5° above the night minimum, increasing the ventilation as the heat increases, not letting the house get too hot then, and throw open the sashes to cool it. It is by committing that mistake that many fail. This information has been given in articles and answers repeatedly, but you appear to have overlooked it; we do not begrudge its repetition, as it will be of service to inexperienced amateurs generally and new readers particularly at this period of the year. The thermometer should be shaded from the sun. April is soon enough for starting Begonias for planting in beds.

**Gooseberry Branches Dying (Somerset).**—It is a long time since we saw more ungenial soil than the samples you have sent. There is no wonder that you have failures. The wonder is that Gooseberries grow at all. It is close, cold, and wet. Certainly it should be drained, as that would result in an admission of air and an increase of temperature. Then lime, ashes, sawdust, and gritty matter of any kind should be added freely, and manure containing much straw should be dug in in the autumn, or when the surface is dry, as such land should never be worked when wet. The proper method of draining would be to form drains 7 yards apart and 3 feet deep, provided—and this is important—a depth of 18 inches of ballast or rubble is placed in for the free percolation of water to the pipes. It would be of little use covering the pipes 3 feet deep with clay. In the absence of hard material

drain from 18 inches to 2 feet deep, covering the pipes with brushwood or the branches of prunings of trees and hedges. Mind that the pipes are placed on a firm base, and level, as if some sink below the others labour will be wasted. Such soil should not be trenched. It is, no doubt, of the same character as that to which Mr. Iggulden alluded when he denounced trenching some months ago. It is sufficiently retentive to hold the necessary nutriment for crops in a foot in depth, and we should break up the sub-soil and leave it, not bring it to the surface. We do not analyse soils, but should not be surprised to find iron in the heavy inert mass. The Currant spray is infested with the bud mite. Raise a clean stock as far as possible from the infested bushes, and these burn as soon as you can spare them.

**Market Gardening (K.).**—There is a good deal in the books you name, the truth of which you will be extremely fortunate if you realise in practice. The best advice we can give you is to consult with some respectable green-grocers, and ascertain from them the vegetables most in demand. You must rely on local custom, and not think of sending produce to Covent Garden; neither must you base your calculations on the published prices, for though they are realised it by no means follows that you can rely on obtaining them whenever you may happen to have produce for sale. As you appear to be without experience in market gardening you will have to work very hard to make any such profits as you appear to anticipate, unless you get possession of extraordinarily good land at a very low rent. As to fruit culture, some few years must necessarily elapse before it can be profitable if you have to plant trees to begin with. Strawberries and Raspberries would give the quickest return, always provided the soil be favourable. Early Potatoes, such as Myatt's Prolific and Beauty of Hebron, may be grown, as Brussels Sprouts, Savoys, Veitch's Autumn Giant Cauliflower, and spring Broccoli can be grown between them. By all means try Shallots and Parsnips, but do not expect to make a fortune from them. Good Asparagus plantations pay well in four years from sowing seed, or two after planting crowns. Early Lettuces and Cabbages pay well, but they must be early, for if late in the market they are of little worth. It is the same with most things. The person who is first in the market gets the best prices. Ellam's Early Cabbage and the Paris White Cos Lettuce are good varieties. Onions pay very well in some soils, so do early Turnips and Carrots; whereas in others the crops are not remunerative. Celery, such as the Leicester Red, well grown, gives a good profit in the hands of some persons; and if you have a certain market for Peas as soon as they are ready they may be grown, but they quickly spoil if not gathered. Prizetaker is a free-bearing and good market variety. Dwarf Kidney Beans pay fairly well sometimes, Scarlet Runners better. You can readily find out by experience the crops that will answer best in the soil and district. Market gardening is not by any means the easy calling it is represented in certain books, and you must make up your mind to have produce to sell at times for which you cannot find a ready market. Some persons succeed admirably, others fail completely, so much depending on the judgment, aptitude, and industry of individuals. The quantity of coke requisite for a given extent of piping depends entirely on the weather and the temperature maintained in a house. If yours is merely a greenhouse we think the quantity you name is more than we should be content to burn, and possibly we would manage with less, so much depending on the stoker.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (J. K.).—We can only name 5, which is Minchull Crab. All the rest were so bruised and discoloured it was impossible to make anything of them. They had no packing. (N. H.).—The labels were all off the fruit sent, so we cannot refer to them by numbers. The Pear is Chaumontel. The green Apple is Winter Greening, and the red one we do not know. (W. H. B.).—Formosa Nonpareil. (H. Hewat Craw).—Your Apple is certainly neither Court of Wick nor Golden Harvey. It most of all resembles Kerry Pippin or Barcelona Pearmain, and we should have considered it to be the former were it not that the season of that variety is long past. We shall endeavour to discover the name, and meanwhile will thank you to inform us whether the oval or the round, specimens of which you sent examples, is the more prevalent.

**Names of Plants.**—We only undertake to name species of plants, no varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (N. H.).—No. 4, Escallonia rubra; 5, Aucuba japonica variegata; 6, Euonymus japonicus variegatus.

## COVENT GARDEN MARKET.—FEBRUARY 17TH.

MARKET has been very dull. A slight improvement in Grapes. Large consignments of Nova Scotia Apples to hand.

## PROFITABLE FARMING.

HARD work, very hard work, is done by the "small farmer" of Sussex. With few exceptions he is his own carter, ploughman, and yardman. Early and late he keeps plodding on. From 5 A.M. in summer and an hour later in winter his day runs on till 8 or 9 P.M. in one incessant round of drudgery. No farm labourer works harder—few so hard, and though he undoubtedly complains loudly of hard times, he takes good care that his receipts shall always show a considerable margin over expenditure in the pleasing guise of his balance at the bank. His method of doing this is very simple: it is just to go without a thing if he finds he cannot afford it. Such self-denial is a life-long habit with him, and it is certainly not regarded as a special virtue.

The "small farmer" who achieves a degree of success superior to his fellows is he who is so fortunate as to have a good wife. The *St. James's Gazette* tells us of one prosperous farmer whose wife "was a very capable woman, who never stopped her work a minute whatever visitors came in, or allowed anyone to hinder her. For many years she made £60 a year by her poultry and eggs; used to start at 4 A.M., with a wheelbarrow filled with chicken food to feed poultry in distant meadows, some half a mile off." Nor is this by any means a solitary example of downright resolute effort on the part of women of this class. We could point to many another with which we are intimately acquainted. We know one notable farmer's wife who, with her two daughters, obtains by the proceeds of her dairy and poultry more than enough to pay the rent of her husband's farm of a hundred acres. It is their habit always to be up in the morning by six; nor are they idle of an evening—with them the sewing machine is a household institution, for the daughters are

proficient in dressmaking, and all their clothing is "home made." It need hardly be said that agricultural depression does not bring ruin in its train to such a family. To them we gladly concede a reasonable reduction of rent with far greater satisfaction than ever can be experienced in doing the same thing for the tenant who affects the "fine gentleman," and demands it as indispensable to enable him to keep up his fox-hunting. We write this in no carping spirit, but we would urge upon every farmer the importance of always living well within his means, and of adapting himself to circumstances. Depend upon it, the man who has the moral courage to do this commands the involuntary respect of all sensible people.

We were recently asked to purchase a farm because the owner said he found he could not afford to keep it; he must sell it and try something else. Now this man had passed the greater part of his life upon this farm, had brought up his family there, and was certainly too old to form fresh habits and take up a new calling readily. We soon saw enough of his affairs to convince us that if only he had sufficient sense and courage to effect a radical reform in his expenses to dispense with the luxury of keeping up false appearances, he might not only retain possession of his property, but also earn enough for the reasonable necessities of life, even under the depression.

One remarkable outcome of the depression is a pronounced development of character. The man of energy becomes more energetic, more thoughtful, more teachable; he will not be beaten. His appeal to his landlord for a reduction of rent is couched in such language, and is accompanied by such a clear statement of his affairs, that respect and due consideration is forthwith accorded him. "If I do fail," says he, "it shall not be through poor farming," and he is precisely the man whose samples of farm produce are among the best in the market, who still obtains the highest prices for them, and it must not be forgotten that now a very little more or less per quarter for corn or per head for live stock makes a vital difference between success or failure.

Be it remembered, too, that in these critical times success in farming really means paying one's way. Agreeable as it undoubtedly is to have a heavy balance at the bank, we certainly do not consider that desirable for the ordinary farmer. His capital should be at work, and should be so apportioned as to be always bringing in some quick returns. Farmers must be on the alert to take advantage of every opportunity, and to step out of the beaten track of their forefathers as occasion may require. It is our desire not only to help them, but to enable them to help themselves in matters great and small, and to be really earnest in all they have to do. A short time ago one of our tenants complained to us that he had 600 bushels of Barley so much discoloured by rain that he had only 15s. a quarter offered him for it. Clearly he could not sell it at such a price. What was he to do? We at once said, "Grind it, and get some pigs to eat it," and we were glad to find that he followed our advice; but we may own to a feeling of surprise that so simple a remedy did not occur to him.

The outlook for farmers is certainly a gloomy one. Wheat is at a ruinously low price. Much of a fine crop of Barley was spoilt by rain, the root crop was in many a district a failure. But, as we have said before, the farmer who had the full advantage of the best modern appliances for harvest work had most, if not all, of his corn cut and stacked before the rain came. So, too, with roots. With early sowing on rich highly cultivated land, the roots had so good a start before the drought set in that the crop suffered very little from it. Remember now, too, that in order to insure, as far as one can do, a full crop of hay the manure must be applied before the expiration of the present month. To wait later is really to court failure. A man may occasionally be successful although he is a little late with his work, but tardy practice does not answer long.

(To be continued.)

## WORK ON THE HOME FARM.

During the prevalence of severe frost we have seen much carting of manure being done, and in some instances in a manner to which we strongly object. No doubt it is advantageous to get manure upon the land just now, but distributed in small heaps or spread broadcast over the surface there is a serious loss of its fertilising gases unless it can forthwith be ploughed in. Where ridge-and-furrow ploughing was done in autumn or early winter in readiness for root culture in spring, the manure may be put in the furrows and then readily covered by passing a double-breasted plough through each ridge; but if it has to remain exposed to the air long before it can be covered the loss in fertility will really prove a serious matter. By all means cart your manure to large heaps upon the land over which it is to be distributed, but do not spread it about till the ploughs can be used. Our own horse work has consisted in drawing chalk and gravel to raise and harden the bottoms of yards and for farm roads. Timber, faggots, and poles have been cleared first of all from the grass land and next from out of the woods. Carting of hay and straw to markets is also being done, for since we have ceased filling our cattle yards in winter the amount realised by the sale of fodder is considerable, and we devote no inconsiderable portion of the money to the purchase of artificial manure. Corn-crushing, root-pulping, chaffing of hay and straw requires some extra labour now, for the breeding flock and hoggets make heavy demands upon our supplies of such food now. The lambing goes on briskly and well. The ewes are having an extra supply of bran and crushed Oats. Feed the ewes well, say we, and do all that is possible to bring on the lambs quickly in view of as speedy a sale as may be. It can answer no good purpose to keep a lot of half-fed animals on any farm, nor is it desirable ever to allow them to fall into poverty of condition. There is, of course, a reasonable limit to the high-pressure system of forcing on young stock, but quick development and early maturity must be our aim now. With cows calving throughout winter at the home farm, it answers well to fatten the calves and dispose of them for veal. On the day of writing this note we have been to a large cattle market and seen some calves only moderately forward in condition realise close upon £5 apiece, and at the same sale Irish shorthorns between two and three years old hardly reached an average of £15 apiece. There can be no question that the younger animals were very much the most profitable. Do not overlook the importance of warmth and shelter to all animals now. Glad, indeed, shall we be when lodges and yards become the rule and not the exception on farms generally. Instead of trying how much exposure to wet and cold can be borne with impunity, it would be better to ascertain the amount of benefit derived from warmth and shelter.

## TRIALS OF AGRICULTURAL MACHINERY AT THE KINVER SEED FARMS.

A GATHERING of about a thousand agriculturists and other spectators took place recently at Messrs. Webb & Sons' farm to see the work compassed by the steam threshing machines of Messrs. Ransomes, Sims, and Jefferies, Ipswich, and also of witnessing a ploughing match with their new digging ploughs. In the digging plough brought under the notice of the farmers of the district yesterday it is claimed that an implement is provided which completely breaks up and pulverises the land, dealing with it very much as if it were spade-dug. This is said to be done with less draught than in the case of an ordinary plough, and one of the best testimonials to the merits of the digging plough is that its use is rapidly extending. It was once said by a wag, when appealed to as to the best way of making the most of the land: "Turn it up on end and plant both sides of it;" but, admitting this is utopian, one of the next best ways to get a good crop must be to thoroughly stir up the soil before the seed is entrusted to it. Nearly a score ploughs, each drawn by a pair of horses, were engaged at the same time in parallel lines of work, and the animation of the scene was more like what would be met with on a big Transatlantic farm than in a quiet corner of plodding England. Half a dozen prizes were offered for competition among the ploughmen, and the awards were made by Mr. J. Giles and Mr. W. Trow at the close of the work, with the quality of which they expressed themselves much pleased. The prizes ranged from £2 in value downwards.

Besides the ploughing competition there was an exhibition of the skill of Messrs. Ransomes' "champion ploughman," Barker. He has taken a host of awards at ploughing matches, and proved himself *facile princeps* in arable work. His deftness was shown with a different class of plough to that already spoken of, the one he steered being a "Newcastle" prize plough. It turns a whole unbroken furrow, as Barker guides it, in a line of almost mathematical precision; and the rows of soil turned over were laid side by side at apparently precisely equal distances, and at precisely the same angle. As a piece of clever and scientific ploughing, there could be no question of Barker's accuracy of eye and hand. The land as ridged up by Newcastle plough is just in the best form of being pulverised by atmospheric action and frost before being planted with cereals. On the other hand, the digging plough tears the ground to pieces in a way that adapts it better for root crops. The immediate crop in view determines the point of the best kind of plough to use, and there is naturally some variation in the implement best adapted for different purposes and different soils.

The trial of threshing machinery took place in the rick yard, and a rick of Webb's Kinver Chevalier Barley was operated upon. The capabilities of the finishing threshing machines were exhibited, the one used being a standard full-sized machine, driven by an eight-horse-power portable engine. As a rule, though machines are called finishing

machines, they often require the grain to be passed through twice in order to secure a clean marketable sample. The machines of which the one at work was a type are intended to complete the whole business in one transaction, and to deliver into the sacks at the mouth of the machine as clean a sample of grain as either buyer or seller could desire. When properly fed the full-sized machine will thresh from 600 to 800 bushels of corn per day of ten hours. During a test taken it was found that the machine threshed a sack of Barley in three minutes and a quarter. The machine in use was, as we have mentioned, a standard full-sized one; but we understand that lighter machines are thought preferable in hilly districts, where the question of transfer from place to place has to be considered. In the course of the proceedings Messrs. Webb entertained the visitors at luncheon in a large tent near the homestead.

## OUR LETTER BOX.

**Prices of Manures (B. B.).**—We can only advise you, as we have advised others, to ascertain prices of artificial manures from local dealers, which are to be found in almost every considerable town in the kingdom. If vendors were to advertise manures unmixed they would increase their sales; if they do not advertise no one can expect us to do so for them.

**Sheep with Swollen Lips (J. M.).**—The tongue which you were good enough to send us had so little inflammation that we hope the disease is already passing away. Blain usually presents itself first of all in the tongue, and attention is attracted to it by a free discharge of saliva, at the outset limpid and inoffensive, but soon becoming thickened by a discharge of purulent matter, and fetid. The inflammation soon spreads, the head and neck become swollen, and there is considerable difficulty in breathing. You would do well to examine the mouths of the whole of the sheep, and if any vesicles are found under or along the sides of the tongue, open all of them with a lancet, then wash the mouth first with warm water, and afterwards with the solution of chloride of lime. The disease is infectious, and due care should be taken to prevent it from spreading to other flocks.

**Permanent Pastures (W.).**—Why lose a year for the sake of a poor crop of Clover? If you intend dressing your poor land with farmyard manure do so at once, plough it in with the Clover, and when the soil is sufficiently dry to enable you to get a fine seed bed, do so without the loss of a day, and then sow the grass seed. If you intend using artificial manure take for an acre half cwt. nitrate of potash, three-quarter cwt. nitrate of soda, half cwt. superphosphate, half cwt. steamed bone flour, well mix, sow immediately after the grass seed, and work in with harrows. This will induce a free strong growth upon the young pasture, and you will be able to fold lambs upon it twice before the end of next September, when the lambs must be withdrawn from it for the winter. By passing lambs quickly over it in folds before any of the grasses run to seed you insure the consumption of the whole of the growth without damage to any of it, and at the same time impart additional fertility to the soil in the most economical way. If in the following summer and autumn you pursue the same practice with sheep, always using folds, you will by the end of the season of active growth have a fairly well-knit pasture suitable either for grazing purposes or hay.

**Artificial Manures (J. H. W.).**—The names cannot be put in plainer English: indeed, to alter them at all would confuse rather than instruct. They are well understood by dealers in manures, and you can procure prices from those in your neighbourhood. We do not suppose you have the means for steaming bone meal, and you may very safely use it as it is. This also answers the letter of "W. C." We can neither quote prices nor recommend dealers who do not advertise their goods. All the constituents referred to in the formula are included in the fish potash manure that is advertised in another column with the prices appended. We intend trying both, and we suspect you will have little to lose by doing the same. We know one is good, and have a strong impression the other is good also, and easily procurable.

## REMARKS.

7th.—Fine, but without bright sunshine.

8th.—Cold and fine, but rather hazy.

9th.—Slight fog early, very dense from 9.30 till about 11.30; slightly foggy during the rest of the day, and intensely cold throughout.

10th.—Dense fog in the first part of the morning; fine and bright after; fog again at sunset and in the evening.

11th.—Dull and foggy all day.

12th.—Rain in the small hours, and slightly foggy with showers throughout the day.

13th.—Dull, with showers early.

A week divided into two periods of typical winter weather—the first dry and cold, with dense fogs at the beginning and close of each day: the second dull, damp, and raw, with almost continuous slight fog. The temperature is about 7° below the average, and the lowest for any week since January, 1881. In London there were three or four days safe skating, a very unusual occurrence in February.—G. SIMONS.

## SPRING PLANTING.

**W**HILE the winter of 1885-1886 cannot, perhaps, be described as of great severity, it has undoubtedly been of protracted duration. It came early and appears to depart reluctantly. The long term of intermittent frost, snow, and wet has been the reverse of advantageous in various ways. Work both in trade, especially the building trade, and on the land having been seriously obstructed, has been inconvenient to capitalists and almost disastrous to operatives. The work in connection with the land that has been the most delayed is that of planting. No doubt the general routine of the farm and the garden has been more or less arrested, but it is to be remembered that a period of frost is specially favourable for the quick and economical conduct of what may be described as work on wheels, which can never be done in the cheapest and best manner in "soft" weather. The frost also has had a beneficial influence on land generally, whether pasture or arable in fields, or dug or undug in gardens; indeed, in the case of very light soils in gardens it is a question if a good frost is not as beneficial as a good digging, and it will be conceded it is both easier and cheaper. When the land is quite clean, and of such a light or sandy nature as to dry quickly and excessively, it will be as well, possibly better, for the majority of crops if it is not dug to any great depth, or only for the sake of appearance and covering any manure that may be added. Even the digging of much heavy land may be postponed with advantage rather than otherwise till dry weather in the spring, as there is nothing gained by forcing on such work under unfavourable conditions, or when the surface is wet. "Dig and crop as you go on," is often the best practice in heavy soil that was not turned up in autumn. A great deal of ordinary digging may therefore be postponed without anything serious occurring if other work of an important character presses, such, for instance, as planting.

There is no doubt that a great deal of planting both of fruit and forest trees would have been done during the past three months if the ground had been dry and open instead of wet or frozen. It is quite certain, too, that it is desirable alike in the interests of owners of estates and of the general community that the more extensive occupation of land with trees should be systematically adopted. There are thousands of acres of comparatively barren, and at present absolutely useless land, in various parts of the country that might be made profitable by the cultivation of Larch and other trees for which the soil is naturally adapted, and it must be very poor and sandy indeed if it will not grow Scotch Fir; also excessively wet if Ash and Poplar will not thrive. The home timber supply is getting scarcer and scarcer, and foreign cargoes will get dearer and dearer. The resources of this country, old as it is, are not nearly developed in the growth of timber, and it is not unlikely that the time will come when something like a panic will take possession of the minds of men on the question, and bitter regrets be experienced that

planting was not extensively conducted a generation previously. The planting of waste land with timber trees that cannot in any other manner be so well turned to profitable account is a matter demanding serious consideration as to the selection of the most appropriate kinds for the soil and locality, then prompt action in planting. Some far-seeing owners of waste land are alive to the importance of occupying it in the manner indicated; but the great fact remains that there are thousands of acres of positively no value now that might be occupied with thrifty plantations that would "grow into money" in the course of a very few years.

It is the same in respect to fruit. More ought to be grown at home, and grown better than at present, or rather the bulk of our market Apples, for instance, ought to be fat and juicy, like those which win prizes at shows. There is no fear of these waiting for customers. They are the produce of healthy trees in generous soil. Nothing, it is said, strikes American visitors to our shores as more strange than either the absence of orchards near homesteads or the half-worn-out old grandmother-like trees that happen to exist. One of those visitors, a most attentive observer, and an admirer of many things in the old country, was impelled to record:—"Notwithstanding England is such a garden, neither did I see any gathering of Apples in October, nor orchards from which to gather them. 'As sure as there are Apples in Herefordshire' seems to be a proverb; yet it is very certain that the orchard is not the institution anywhere in Britain that it is in America, or so prominent a feature in the landscape." That this is in great measure due to the state of the law can scarcely be disputed. Landowners as a rule (for there are a few exceptions) will not plant fruit trees, not even in some instances to adequately meet the requirements of their establishments, and tenants, except under long leases, are not justified in doing so in any systematic manner, because they would be sowing for others to reap who are not of their own kin, besides subjecting themselves to the extraordinary penalty, the truly "extraordinary tithe." Yet, notwithstanding those natural, or unnatural, impediments, more fruit trees are being planted than formerly, and will be planted, as a set-off against past negligence, and as a necessity for maintaining even a moderate supply of fruit, which old trees cannot much longer possibly afford, to say nothing about the inferior varieties that cumber the ground. The wholesomeness of fruit, its nutritious properties and medicinal qualities, is being more and more appreciated, and the consumption will increase all the more rapidly as the quality of the produces increases under better culture and the exercise of sound judgment in the selection of kinds and varieties that meet alike the public taste and that thrive best in certain localities, or in which they appear to be naturally at home.

There should not only be no cessation in planting fruit trees so long as land remains to be occupied by them, but the work should be pressed on with all the force available. It has become almost a habit for writers to urge the importance of autumn planting with the object of "saving a season." Not a word is here said against planting fruit trees in November, and in the case of moving large trees from one position to another in the same garden a season may easily be gained by doing the work in the autumn; but in the case of young trees, fruit, forest, or ornamental, obtained from nurseries, it is very questionable indeed if a season is gained by the practice recommended, whereas it is very certain a season may be easily lost by omitting to plant now—that is deferring the work till another year, and obstacles then intervening, as they do every autumn, to prevent the work being done in November. The advantage of planting in autumn consists in the warmth still lingering in the soil inciting the formation of fresh roots before winter; but if the work drags on, as it often must do, through December, there is no rooting before winter, and there is nothing gained over planting in February, or even early March in a backward season, provided special care is taken to prevent the roots of

the trees drying in transit, planting is well and carefully done, and pruning prompt and rather severe.

Dryness of the roots of trees obtained and planted in spring is the primary cause of failure, the trees either dying or struggling to keep alive instead of growing satisfactorily. It has fallen to my lot to see thousands of Larch and other trees ruined through the exposure of their roots during a long journey in spring when a dry air and brisk wind prevailed. Trees selected from the bulk that by some accidental cause had not their roots dried have been planted and grew; an equal number with dried roots planted between them died. When trees arrive with the fibrous roots resembling dried hay, and there is no alternative but to accept them, the best plan that can be adopted is to immerse the bundles in a pond for two or three days. Many of the fibres will probably freshen, and those that do not should be cut clean off to where the stouter roots are fresh, and plant before these get dry again.

When trees are purchased in the spring, moist roots on arrival should be a condition of acceptance; and when they are kept moist till planted under favourable conditions fruit and forest trees of all kinds, Roses and shrubs will grow as well planted now and during the next few weeks as if they had been put in in December just before the frost. I had some Roses planted in the month just mentioned but the work could not be completed, and the remainder are still "laid in." They will be planted soon, and I am as positive as I can be of anything that they will grow just as well as the others; and so they would if they were fruit trees.

Plant trees now, but do not prune till the sap rises in spring, is advice often heard. It is given on the assumption that leaving the branches entire, or nearly so, accelerates the production of roots. This might possibly be so if the branches were always wet, but it certainly is not if they are exposed to several days of drying easterly winds that are so common in early spring. The wind acting on the surface of the bark extracts the moisture from it, and the greater the surface exposed the greater is the loss. Some Roses were planted last February, with growths ranging from 2 to 4 feet long. Some of them were not pruned at all, others being shortened more than half their length, and cut more closely towards the end of March. The pruned plants grew and flowered satisfactorily; some of the others died, and not one made anything approaching vigorous growth. The dry winds acting on the long shoots did the mischief. This only confirmed previous experience. Keep the roots of trees moist in transit, or while out of the ground; plant carefully now, or when the ground and weather are favourable; stake securely, prune, and with such after attention as circumstances may dictate trees will grow well. In the case of standards planted against south walls, or in fact, anywhere else, the advantage of wrapping damp haybands round the stems, and keeping them damp, is perhaps not sufficiently appreciated by everybody.—EXPERIENTIA DOCET.

### ECONOMICAL AND SUCCESSFUL DAHLIA CULTURE.

MANY people object to growing Dahlias because they occupy so much ground. When I began cultivating them I felt I could not spare the ground, but I overcame that difficulty by planting early Potatoes on it. I always grow them on the same ground year after year. One reason is because I cannot get shelter from the wind in any other part of my garden; and the other is, the ground being manured and the plants mulched every year, it is in better condition to grow the plants to perfection.

My method of utilising the ground to best advantage is to get it well manured and dug by the middle of March, and then draw deep drills 4 feet asunder to plant the Potatoes in. They should be well sprouted and a short stake placed at the end of each row. I find Myatt's Prolific the best, and it is astonishing what a heavy crop I get in this manner. They should have their final hoeing before the Dahlias are planted—that is, the last week in May or first in June. If the weather should be frosty the latter date will be the best. I drive the stakes for Dahlias between the rows 5 feet apart and put

the plants about 6 inches from the stakes. As soon as the planting is done I get some sturdy Lettuce plants, and plant two or three between each pair of Dahlias to attract the slugs. These are visited by "moonlight" if available. Nothing but these nocturnal walks will cope with the pests.

About the first week in July I commence lifting the Potatoes for use as required, taking up those first that are likely to crowd the Dahlias. By the end of the month I take all the Potatoes up, level the ground, mulch the plants, and place a stake to each strong shoot, cutting out the weak ones, and well mulch the plants, beginning to disbud as soon as the buds are visible. After this time I water the plants twice a week and sprinkle the foliage every night if I can find time. I always endeavour to get buds on each plant in different stages of growth to have blooms for all the shows I want to exhibit at. I find those just unfolding their petals a fortnight before the date they are required are mostly in form for show.

All cultivators find earwigs very troublesome. I can never find time for wrapping them, but put all the best shaped buds into muslin bags as soon as they begin to show colour, taking them off a day or two before the show, and, tying a little moss below the blooms, they very seldom get past that. I am most particular at this stage to keep the plants watered over the foliage every night. They do not like getting on the wet foliage, and clear water does not hurt the blooms. When I first began exhibiting people used to talk very much about dressing the blooms. I have lived long enough to know if the flowers are not well grown no amount of dressing will make them fit for exhibition. If by chance a petal should get eaten or split it should be removed with the tweezers and the adjoining ones pressed round to fill up the space.

I hope as the season advances our veteran grower, "H. G." will favour us with some cultural notes; but Dahlia growers have little time for writing from June till the middle of September. And, now, Mr. Editor, if any of your readers object to this system of cultivation, I have only to say that by it in 1884 I succeeded in gaining eleven first and two second prizes, including a first at the National Show against fourteen competitors. Last year I did not exhibit at so many shows, but was awarded seven first, three second, and one third prize, and had the premier bloom at the National Show.

I hope to see the above-named Society in a more flourishing state. At present it is languishing for lack of funds. I append twenty-four Show and twelve Fancy varieties that will come a good size with moderate cultivation and suitable for beginners, which is the object of my troubling you with this.

Twenty-four Show varieties, in order of merit:—Mrs. Gladstone, Hon. Mrs. J. Wyndham, James Cocker, John Henshaw, Goldfinder, Joseph Ashby, Clara, Vice-President, Ethel Britton, Wm. Rawlings, Flag of Truce, Earl of Ravensworth, Miss Henshaw, Sunbeam, John N. Keynes, George Rawlings, Mrs. Jeffard, Constancy, Julia Wyatt, Miss Cannell, Mrs. Langtry, Prince of Denmark, Hope, and Rev. J. Godday.

Twelve Fancy varieties, in order of merit:—Flora Wyatt, Professor Fawcett, Romeo, Rev. J. B. M. Camm, Lotty Eckford, Grand Sultan, Mrs. N. Halls, Fanny Stuart, John Forbes, Miss Browning, Chorister, and Oracle.—J. T.

### NOTES ON TOMATO CULTURE.

THAT Tomatoes are "grown" in some establishments and "cultivated" in others is a fact well known to many members of the profession, especially those who are in the habit of visiting gardens, both large and small, and comparing the results obtained by this or by that practice.

Much diversity of opinion prevails in respect to propagating Tomatoes either by cuttings or seeds. Having at one time a decided inclination for cuttings, it was our practice to get a large stock struck early in the autumn for winter and spring fruiting; but were not long in relinquishing that system when a very decided decrease in our supply was apparent—in one instance owing to the cuttings developing the disease (Peronospora), and in the other to clubbing of the root, the consequence being the dying of the points of the shoots in a very aggravating manner as the spring advanced. But since discarding all old plants and cuttings therefrom our difficulties have considerably diminished.

We have found it a good plan to sow the seed in pans the second week in August, and place the seedlings into 4-inch pots as soon as ready, by about the middle of September, when the strongest are selected for shifting into 7-inch pots, using some sound loam for that purpose, fibrous loam not being necessary. Moderately firm potting will be essential to promote a sturdy and fruitful growth. A stake not more than 18 inches long is supplied to each, and the stems secured thereto, when they are removed to a light airy position close to the glass, generally a shelf in an early Peach house. In a short time they will all simultaneously produce trusses of

bloom, which with proper attention to watering and an occasional tap of the stems set from four to six good fruits. As soon as they are swelling fairly the plants are removed to a house in which a mean temperature of 65° is maintained. Here narrow borders of loose bricks filled with loam are formed, the dimensions generally being 18 inches wide and 12 inches deep, in front of and running the length of the house, the plants being turned out 1 foot apart and tied to the trellis. All side shoots being strictly removed no overcrowding or confusion of growth can occur. Under these conditions the fruits swell rapidly to a large size, and with an average amount of sun can be depended on to supply several good dishes during the latter part of December and onwards. Those plants remaining in 4-inch pots after the first selection are shifted into 6-inch pots somewhat later, and so remain in a light position in an intermediate house until early in the new year, when they are treated similarly to the foregoing, and the result is abundance of early fruits of large size and good quality.

Of the superiority of the single-stem or cordon system over the spreading or scrambling mode of training there is not, in my estimation, a shadow of doubt. A striking instance of the success of this system I recollect seeing a season or two ago illustrated in a very forcible manner in the gardens of Lord Wolverton at Iwerne Minster, Dorset, where, in one of the extensive ranges of glass Mr. Davidson had recently converted a cold orchard house into a heated vinery, and, being the first year, had planted the back wall (some 60 feet long and 13 feet high) with Tomatoes on the cordon system. The result was Tomatoes in the most extravagant abundance. The sight of the large fruits hanging in enormous clusters one above the other, which to my mind resembled strings of Onions, was a sight not easily forgotten.

Such convenience is so seldom attainable that a more generally practicable method is to place two strong plants in a half-bushel pot, with a good space left for watering, and stand close together on the staging at the ends of vineries or Peach houses and such-like places where most light can be obtained, and secure the stems to wires fixed to the sashes. In late vineries they can be staked upright and the pots placed in rows on the inside border, where, after perfecting a crop of fruit before the shade from the Vine foliage becomes too dense, they can be removed to a warm corner outside, and the pots being well packed round with plenty of long stable manure and the stems fastened to the wall, they will quickly produce a further supply of fruit and continue to do so until the autumn.

Where a house is devoted to their culture, the use of borders or pits formed with loose bricks has much to recommend it in preference to pots, the chief feature being the ready means afforded of giving the plants fresh root room when they show signs of exhaustion by taking down one or both sides of the pit and placing the bricks at such a distance as seems desirable, filling the intervening spaces with fresh soil, which the roots will soon take possession of, and renewed vigour and fruitfulness will result.

In whatever position, or under whatever system the plants are grown, a liberal supply of water—the chief essential to their well-being—must constantly be applied according to requirements. As a pot plant I do not know of another so thirsty as the Tomato, which semi-aquatic propensity is, I suppose, to be accounted for in the peculiar formation of the leaves being such as to enable them to rapidly evaporate the supplies administered. On one occasion I tried an experiment with the supposition of the Tomato being a semi-aquatic plant, by placing four in a zinc trough 3 feet long, 15 inches wide, and 5 inches deep, partially filled with soil and perfectly watertight, and trained on the cordon system to the back wall of a vinery in a light position. From the first the plants made satisfactory progress, set and ripened large clusters of fruit, and succeeded generally as satisfactorily as others in the same house in half bushel pots. An interesting feature in the experiment was observing the rapidity with which they would imbibe the water that was often standing half an inch above the soil after watering, there being, of course, no outlet for it. I may add that they did not require watering more frequently than those in large pots, and also that liquid manure was occasionally administered. Many gardening friends on seeing them evinced considerable surprise at the small amount of soil, the more so as there were but few surface roots, as to doubt the fact of the roots being confined within the trough, and only on lifting it clear of the ledge on which it stood would be convinced, when they came to the same conclusion as myself, that it is not the amount of soil that is of so much importance as the amount of moisture contained therein. Since performing this experiment I have been informed that a member of the profession holding a high position in regard to horticultural matters was pursuing experiments in somewhat the same line—viz., by rendering watertight the bottoms of the pots with a layer of cement. What the results of his experiments are, I am sure, would

be welcomed by many interested in the culture of this deservedly popular fruit.

As to varieties, many would-be cultivators are often puzzled to determine which to select of the multitude of sorts, which, with such marvellous descriptions attached (correct or otherwise) swell the lists of many seed-vendors' catalogues. Amongst a number of sorts grown on trial, Dedham Favourite has proved itself a superior and reliable variety for summer or winter under glass and outside during summer, a good cropper, handsome in appearance, and excellent in quality.—M. COOMBE.

## THE PRIMULAS.

(Continued from page 117.)

*P. OLGE*, *Rgl.*—A new species, discovered by Dr. Regel of St Petersburg, and figured by him in the "Flora Turkestanica." It was at one time in cultivation in the St. Petersburg Botanic Garden, but we believe has since been lost; a fresh supply of seed has, however, been obtained, and we may soon hope to see it in English gardens. It is said to be nearly allied to *P. nivalis*, *Pall.*, and judging from the coloured drawing in the above work it promises to be a great acquisition to our list of Primulas. It is found at about the same elevation as *nivalis*, which fact may be a guide to its culture. It grows 3 or 4 inches in height, terminating in a few-flowered umbel of charming rosy-lilac flowers resembling but larger than *P. sibirica*; the blooms are over half an inch in diameter, leaves obovate oblong, tapering to narrow winged petioles, glabrous, and shiny on both surfaces. Native of the high mountains of Western Turkestan at 7 to 12,000 feet above sea level.

*P. PALINURI*, *Petag*—Of the few Primroses having a truly arborescent habit of growth, not even excepting the charming little Californian *P. suffrutescens*, none approach this gigantic species (which has been not inaptly compared to a luxuriant plant of *Sempervivum arboreum*), either in height or proportion of stem when it is allowed to fully develop itself. It is perhaps the least amenable to pot culture of all the Primulas we are acquainted with, and although it may be had to do well for a year or so the final result is seldom if ever satisfactory, the flowering being much impeded. When bound in small confines of a pot the leaves curl, rust, and become disfigured, the plant being generally unsightly before flowering time, if it develops flowers at all. The real cause of this may have been insufficient food, as it seems to be a voracious feeder, and as large pots are required to grow it well this is not always convenient where space under cover is limited. The best plan, it would appear, to get the full advantage of its flowers as it opens towards the end of February and beginning of March would be to plant it in a border in the conservatory as recommended for *P. japonica*. If a sheltered spot can be found in the open it will do well; and even in the ordinary border in late seasons it rarely opens its flowers until all danger is past. A sunny position should be chosen, and in the growing season it may be attended to with abundance of water. *P. Palinuri* is supposed to have something to do with the present development of the garden *Auricula*, as well as *P. Auricula* and *P. pubescens*, and as far as appearances go it is not at all unlikely. It has generally a stem rising several inches above the ground, deeply marked with the old scars of the former leaves, an inch or more in diameter, the fresh leaves forming tufts at the summit from 4 to 6 inches long, obovate spatulate, irregularly and deeply toothed at the margin, to where it tapers sharply to the base, glabrous (not shiny) and without farina on either side. The scape, instead of coming from the growing point, as in most of the others, proceeds from the base of the lower leaves carrying a head of from twenty to forty large pale or lemon yellow flowers, the calices densely covered with powder. A native of *Palinuri*, near Salerno, Italy, and flowering March and April.

*P. PARRYI*, *Gray*.—Undoubtedly the handsomest of all the New World Primroses, and indeed comparing favourably with the much-esteemed *P. japonica* and *P. nivalis*. It was first introduced by Mr. Thompson of Ipswich about 1861, who distributed it freely, but without much success as regards cultivation, as it became almost extinct soon after, and was reintroduced a dozen years later by Mr. Backhouse of York, and by whom it was flowered in 1871. We also saw it in flower in the new rockery at Kew last year. Perhaps the failures to flower, and even to grow it, may be attributed more to the want of water than adverse climate and other effects, for since following Dr. Parry's directions, planting it beside a pool or stream in the coldest and most exposed place available, it has grown vigorously, and two of the two-year-old plants flowered last year. It supplies a colour much wanted in Primulas, and under the above conditions it gives no trouble whatever. It appears to be widely distributed, and from this fact Dr. Gray suggests the possibility of its being a form of *P. nivalis*, which indeed it much resembles. The flower scape grows about a foot high from the middle of a dense tuft

of oblong or oblong lanceolate succulent leaves, varying in length from 4 inches to a foot, obscurely toothed, or in young leaves quite entire at the margins. The flowers are collected in a loose head surrounded at the base by short pointed bracts, varying from a dozen to twenty, an inch or more in diameter, bright red or crimson purple, with a large yellow eye. Calyx cup-shaped, glandular, and often reddish tinted. It is found on the margins of Alpine brooks, through the higher rocky mountains of Colorado to those of Nevada, and even to Arizona on Mount Lincoln as high as 13,000 feet above sea level. It flowers May and June.

*P. PEDEMONTANA*, *Thom.*—The Piedmontese Primrose seems to be one of those difficult customers anent which doctors differ. All the leading authorities seem to agree to its belonging to the Auricula group, and a close ally of *P. viscosa*, though all differ as to its true position, and whether it deserves specific distinction. In De Candolle's "Prod." it is included under *P. villosa*, *Jacq.* In Reichenbach's "Fl. Germanica" it receives specific distinction, with *P. pubescens*, *Jacq.*, and *P. villosa*, *Jacq.*, as synonyms. In Wyman's "Conspectus Europæus" it is also made a species, with *P. Bonjeana*, *Heug.*, as a syn.; while in Mr. Baker's preliminary list it is included under *viscosa*, *Vill.*, and which I believe is made to include *P. villosa*, *Jacq.*, but not *P. pubescens*, *Jacq.*

So far as we have noticed this plant under cultivation as regards appearance and habit of growth we would be inclined to isolate it

Fig. 24.—*Primula pedemontana*

Fig. 25.—*P. pedemontana* var.

from all the others, for however near in botanical affinity it may be to *P. viscosa*, which is made to include a host of plants which gardeners consider distinct, as a garden plant it is distinct, so much so as to warrant a separate name. It would seem to be a variable plant under certain conditions; hairy or without hairs; in some almost entire leaves, while others are distinctly dentate, those received from Mount Cenis being hairy with the margins almost entire, while those brought home by Mr. Maw from the Piedmont have entire leaves almost devoid of hairs, and resembling *P. integrifolia* in habit. It is an admirable plant for the rockery, where it thrives well on a western exposure in rich shallow soil well drained, and where it never fails to give an abundance of flowers. The rosettes of leaves are formed close to the ground; leaves oblong or obovate, obtusely toothed or not, the margins covered with glandular hairs, in some few. The flower stem rises 1 or 2 inches high, carrying a large globular head of medium-sized pretty rose-purple flowers, often pale lilac with a yellowish centre. It flowers with us in April. Native habitats high Alps of Piedmont and Switzerland, where it is said to be one of the most lovely plants of those regions. Increased by division. Syn., *P. Bonjeana*, *Heug.* It is also suggested as being a hybrid *P. hirsuta* × *glutinosa*. There seems to be nothing, however, in favour of this.

*P. PENDULIFLORA*, *A. Kern*, we have not seen in flower. In leaf it much resembles *P. sikkimensis*, and is doing well with similar treatment.

*P. PETIOLARIS*, *Wall.*—An Indian species of extreme variability, if one may judge by the numerous varieties to which it has given rise, and likely in the hands of hybridists and careful cultivators to give a fresh lease to this class of plants. The leaves are mealy

or not, varying from 2 to 10 inches long, ragged, toothed, or crenate, and of two distinct forms often on the same plant, either broad obovate, without stalks, and narrowed into a winged petiole, or elliptic or cordate on long slender stalks. The flower stalks are about a foot high, surmounted with numerous large, purple, white, or pink flowers. It likes shade in a rather damp peaty soil, flowering in autumn. Temperate Himalayas Simla to Bhotan, at from 4 to 14,000 feet above the sea level. All the forms or varieties are said to run into one another in all sorts of ways. Syn., *P. cushia*, *Hamilt.*; *P. tridentata*, *Don*; *P. sessilis*, *Roxb.* Varieties, *Nana*, *Stracheyi*, *pulverulenta*, *sulphurea*, *scapigera*, and *Edgeworthii*.

*P. PEYRITSCHII*, *Stein*, is said to be a hybrid (*P. sub-Auricula* × *viscosa*, *Stein*), and answers to the *P. viscosa* var. major of English gardens. It seems to us no more than a robust variety of *P. viscosa*, and will be treated along with that species.—D.

## VARIETIES OF MELONS.

LEST Mr. Iggulden should think silence discourteous I accede to his request, though I do not claim any special knowledge of Melon lore. During some years past I have only grown named varieties as a test of my own seedlings, and I have grown or seen most if not all those honoured with a certificate by the Royal Horticultural Society, in order to estimate the advance made in constitution, free bearing, size, appearance, and quality, and to transfer these advantages to my seedlings by cross-fertilisation.

Those that have struck me as highly deserving of the honour of a certificate and pass to public favour, I have found to be Little Heath for hardiness, Golden Gem, Eastnor Castle, Read's Scarlet-flesh, Colston Basset, Exquisite, William Tillery, High Cross, and Blenheim Orange. All are first-class fruits, great advances in size and appearance on older varieties, but in quality I do not think any advance whatever has been made—none in green-flesh having the high quality of Egyptian or Pine Apple, and in scarlet-flesh varieties Scarlet Gem is unapproached. I do not wish it to go forth that an Egyptian is to be preferred to William Tillery, or a Scarlet Gem to a Blenheim Orange from an economic point of view, but as a connoisseur there is no question as to which way the leaning would be. By increasing size we lose quality, though some hold the contrary opinion, alleging that cultivation and quality go together, though it would not require any great effort to prove the falsity of such reasoning in Apples, Pears, Plums, Grapes, and especially Melons. This is often exemplified in a marked manner on the exhibition table, a medium-sized fruit of some old and neglected variety carrying off the prize from very much larger and finer-looking fruit. I, however, like something to look at—a handsome shape, whether round or oval, and beautiful in colour, netting, and ribbing. Such make a show at table and are esteemed.

Melons, as most growers are aware, run in types. The types, however, are so intermixed by cross-fertilisation as to be somewhat difficult of recognition, and some are very apt to revert back to the type, though seldom all at once, but in gradations of the forms on both sides of the parentage, advances, so far as I have observed, being on the male side, whilst reversions take place for the most part on that of the female. Beechwood is almost the only original Melon now cultivated, though we occasionally see Egyptian, Pine Apple, and Cashmerc. Cantaloup is seldom seen, or Rock, and Windsor rarely puts in appearance. The latter types, however, are common enough in scarlet-flesh, indicated by the round fruit and the ribs, whilst the Egyptian is shown by the stripes or bands dividing the ribs; indeed the parentage of most is legibly marked on the surface, or sufficiently to admit of an identification of their origin.

Beechwood, originally from Persia, is an oval fruit and netted, which by cultivation developed into a bluntly oval fruit, and in good examples becomes almost round; in fact I have had it quite round, which I particularly wish to note, as all Melons advance in proportion as they put on the round or spherical form. Oval Melons cease being pointed and become blunt-ended, or what we term bluntly oval; and round Melons cease to have the ends flattened, and become as rotund at the ends as in the middle. This alone results from cultivation and selection; indeed quite as much is effected by selection of the highest forms as by cross fertilisation, the latter being very tantalising when we come to in-and-in-breeding, everything depending upon the selections.

Beechwood crossed with Victory of Bath (a form of Bromham Hall) resulted in Eastnor Castle, and this, when care is taken in selecting the seed from the bluntly oval and well-netted fruits, is an excellent variety, but it has a tendency to give pointed oval fruit, ribbed, sparsely or not netted, and the flesh of this form is coarse, soft, and poor in flavour. The latter is a reversion to some type clearly on the female side in form, whilst the loss of appearance is on the male side; and reversions always are marked by vigour of constitution, being inherent in the female, though a languishing plant may be rejuvenated by crossing with a vigorous variety. Beech-

wood crossed with Read's Scarlet-flesh gave a round coarsely netted scarlet-fleshed fruit, and a green flesh even more coarsely netted, neither having any quality of note. Beechwood × Read's Scarlet-flesh × Victory of Bath gave several forms, one a round fruit, closely and evenly netted, flesh green, rich and good, very free bearing, and hardy constitution. This I named North Durham (Seedling No. 1), and sent fruit to the Fruit Committee; but it was passed, therefore I suppose worthless, though it was liked better than any named sort by my employers and their friends. I have flattering accounts of it from those to whom I have given seeds, and I still find it unequalled as a green flesh of handsome appearance, pleasing quality, free cropping, and healthiness of plant for frame culture.

Beechwood × Read's × Victory of Bath × William Tillery gave a bluntly oval fruit, slightly ribbed, banded or quartered like Egyptian, finely netted, very handsome, flesh green and highly flavoured, even to cloyishness; and though free in growth and setting, it is tender, being very susceptible to damp, and subject to exudation from the whole plant and fruit, a peculiar characteristic of the Cashmere, Afghan, and Ispahan Melons. The bands between the ribs are greyish or silvery green, as in Egyptian. It requires dry or house culture, being unsuitable for moist or frame culture. This I named J. Wright (No. 3 Seedling), from his known preference for Beechwood, it clearly being an amalgam of Persian and Egyptian Melons.

I crossed Golden Gem with Read's Scarlet-flesh, and obtained a very beautiful fruit, bright gold in colour, the white netting being very much more decided than in Golden Gem. Flesh salmon, flavour poor in summer, but in autumn rich. Though both the parents were round the fruit is oval in shape, like Ispahan. It is very decided in character, and is a reversion on the female or Golden Gem side towards the original, Golden Gem by its exudations alike from plant and fruit being of Cashmerian origin. It also gave a variety with white flesh. With a view to obtaining a hardy-constituted Melon I crossed Little Heath (which, though a much-abused variety, is very serviceable for cold frame culture) with Beechwood, in view of a green flesh, with the hardy character of Little Heath, with a satisfactory result; but those not caring for Little Heath would not take to this, as the quality is not high as compared with some other varieties, though when well ripened I have found both Little Heath and the cross-bred seedling from it excellent.

Earl of Beaconsfield, a sorry edition of that mongrel Netted Victory, both remarkable for the absence of netting, and having a coarse soft flesh, I crossed with North Durham, and have a large, round, ribbed fruit, heavily netted, flesh green and highly flavoured. It is a very free, early, and continuous bearer, doing well under frame treatment. It ought to make a good market sort. I named it W. Iggulden (Seedling No. 6), out of compliment to his expressed liking for a netted Victory of Bath. The ribs are those of Bromham Hall, and its grey bands are Egyptian, though there is none of its blood in the parentage, but I conjecture Bromham Hall resulted from crossing Cantaloup with Egyptian.

Beechwood × Golden Perfection (still one of the very best Melons) resulted in an oval, coarsely netted, green flesh, of high flavour. Pine Apple × Osmaston Manor gave a scarlet flesh, very solid, high flavour, finely netted fruit. Pine Apple × Eastnor afforded a green flesh, high quality, very slightly netted fruit; this I crossed with North Durham so as to secure a well-netted handsomer fruit. Eastnor Castle × Exquisite presented a green flesh, as might be expected, of very high flavour. Blunsdon Abbey × Pine Apple × Eastnor Castle gave a bluntly oval fruit, sparsely netted, and sweet. I mention these as I shall refer to them again presently; but to continue it is necessary to state that I at one time grew Moreton Hall, a small bluntly oval fruit, red flesh, very solid, and when well ripened excellent flavoured; but it cracked fearfully, and to cure this crossed with Ferme's Seedling and Oulton Park. I did not like the result of the Ferme Seedling, but the Oulton Park gave a fruit that did not crack, and was very closely netted. The seeds were brought out day after day through the fruit, surpassing all others in quality. I named it Grinkle, yet it being so small, scarcely a pound weight, it was crossed with Colston Bassett, still one of the very best, and had a bluntly oval fruit, coarsely netted, in both scarlet and green flesh, and indifferent flavour. The green, or rather white, flesh being selected it was crossed with Golden Gem, having a beautiful-looking fruit, gold, covered with white netting, and a flesh first green next the rind, then pink, and white next the core—seed cavity pink. It was of no flavour, therefore crossed it with Exquisite, which resulted in a round or very blunt oval, coarsely netted, heavy fruit—i.e., for its size, 2 to 3 lbs., flesh green, firm, melting, and very rich. I named it North York (Seedling No. 2), but nobody liked it, evidence of my peculiar taste in Melons at least, for I do not find it differ from other fruits. Moreton Hall × Oulton Park × Colston Bassett × Golden Gem × Beechwood has a small fruit; flesh white, tinged with pink. Moreton Hall, up to and including Golden Gem

× Pine Apple × Eastnor Castle, furnished a well-netted green flesh of high flavour.

I come to an amalgamation of North Durham × North York, green flesh, solid, 2 to 3 lbs., coarsely netted, round, named Our Journal (Seedling No. 4); Pine Apple × Osmaston Manor × North York (Seedling No. 7); female North Durham × male Pine Apple × Eastnor Castle (Seedling No. 8); female Osmaston Manor × Pine Apple × male Pine Apple × Eastnor Castle (Seedling No. 9); female Pine Apple × Eastnor Castle × male North Durham (Seedling No. 11). The three last it will be obvious to get size in combination with quality, and to get quality, irrespective of appearance; female Blunsdon Abbey × Pine Apple × Eastnor Castle × male North York (Seedling No. 12). I do not suppose anybody would care to grow any of these, and if inclined to follow such a system of in-and-in-breeding I advisedly say "don't." True we get capital varieties always, but no reliance can be placed on any of them, though by selection of those most constant in character something may result with a continuance true to character. The best that can be said of them is "very interesting to growers of their own Melons." Golden Queen × Moreton Hall to Golden Gem inclusive (Seedling No. 10) as might be expected is very variable.

To give stamina to J. Wright as a frame Melon I crossed it with North Durham (resulting in Seedling No. 5), also with High Cross, as there is no difficulty in getting quality in hot-water-heated structures; but in frames it is very different, so much being dependent on the weather at the time of ripening. Though we have some very excellent varieties in scarlet flesh, none of them has given anything like the same satisfaction as green-flesh Melons; and as I consider High Cross is one of the very finest, taking size, appearance, quality, free bearing, and constitution into consideration, I crossed it with Blenheim Orange, resulting in a scarlet flesh (Seedling No. 13), the counterpiece of High Cross, having the advantage of ripening early. I sent fruit to the Fruit Committee in 1884, and was told "the Committee did not think it distinct from other varieties in cultivation to merit a certificate." Perhaps not; but it is distinct enough to fetch 1s. more each in Covent Garden Market than any other Melon sent there by a grower for sale; and as it gives quite as many fruits in the space of other plants, it means 4s. to 6s. per light more—a consideration that tells with growers. It will, I think, suit our friend Mr. Iggulden, especially as he is not pleased with scarlet-flesh varieties so far, and it will keep several days without deterioration, having a hard rind, therefore not constantly giving off aroma and flavour with it as in the soft-rinded varieties. To get at a keeping Melon I crossed Sedar (an African) with North Durham, and have a large bluntly oval fruit, which will keep three weeks; but the flavour is poor, though some say it is excellent. It is too large for general culture, and crossed with Cashmere might be rendered presentable at an aldermanic dinner. It is constitutionally tender, given to exudation and canker. I have worked with other material, but the result was neither interesting nor desirable. Of varieties that I have not grown, though seen growing, Hero of Lockinge appeared an excellent sort. Were I to take to growing named sorts I should select \*Eastnor Castle, Golden Perfection, and High Cross in green flesh; \*Blenheim Orange, Read's Scarlet-flesh, and Scarlet Premier. If only one kind of each were wanted select those distinguished by a star, but if large fruit of Blenheim Orange is wanted the plants must not be allowed fruit on the first laterals, getting a strong plant, and thinning to three or four fruits on a plant.

Not many of the present race of Melons are directly descended from Egyptian. Bailey's Green-flesh was decidedly of that type, being in fact an enlarged edition, and a most superb kind it were, better far in flavour than any green-flesh now in existence. The only one at all like it is The Squire, which, however, appears to have lost in quality with the gain in size. Another form of Melon which appears to be losing favour is that represented by Heckfield and Queen Emma, both of which are of large size, very highly perfumed, and excellent quality. They have capital constitutions and are very free. Considering their firmness of flesh, I think it likely that crossed with a hard-rinded variety a keeping sort would in all probability result.

There is one other desideratum, and very much overlooked in the raising of varieties—viz., the obtaining of those with hardier constitutions. Little Heath is the hardiest I know in scarlet-flesh and Dell's in green-flesh. The plant is very healthy, the foliage small in relation to the size of the fruit, free setters, and swelling kindly; perfection as regards fruiting. Royal Horticultural Prize, green-flesh, and Duke of Edinburgh, scarlet-flesh, also are very free and hardy constitutions, but though the type is clearly defined in Little Heath and Duke of Edinburgh, which is certainly Cantaloup, I cannot make out Horticultural Prize or Dell's only to having some of blood of the pointed oval smooth form of Beechwood. Anyway, there is raw material for the manufacture of a fine fabric, only the constitutional properties can be retained.

The only one of somewhat recent date that showed any trace of the Black or Dutch Rock was Cirencester Prize; but whether anything constitutionally could be evolved out of these is matter for experiment, and I think highly probable. We want hardier varieties that could be supplied to the multitude as plentifully and cheaply as Vegetable Marrows.—G. ABBEY.

### MANURE FOR ORCHIDS.

DURING recent years some discussion has been devoted to the question whether Orchids are benefited by the application of manure or not, and though much has been said on both sides, yet it does not appear that any very satisfactory experiments have been undertaken or recorded as bearing upon the matter. For some Orchids, such as *Cypripedium insigne*, *Dendrobium nobile*, and *Calanthe vestita* and *Veitchi*, manure has long been employed, both in a solid form and as a liquid, in ordinary garden culture with favourable results, but it has been considered as absolutely unnecessary for other Orchids, if not positively injurious, and not without some reason. The majority of Orchids, but especially the epiphytal species, have extremely delicate fleshy roots, and nothing could be more likely to injure them than contact with crude strong manure in their compost. In fact, valuable plants have been so injured by injudicious application of strong stimulants, and the result has caused a prejudice against the employment of manurial agents in Orchid culture. When the value of plants is counted in guineas it is necessary to be cautious in such matters, or a small fortune may be soon lost. Nurserymen do not care about undertaking experiments that may prove very costly, and they prefer leaving them to amateurs who have more leisure for the purpose, and who probably would be less concerned at the loss of a few plants. Yet there are some experienced Orchid nurserymen who fully believe in the efficacy of manures used discreetly in small quantities, and who have strongly advised amateurs to make more experiments, with the object of proving how far this is the case. We know that tropical epiphytal Orchids are found growing in positions where the atmosphere must be full of the gases arising from the rapidly decaying vegetation beneath them; birds, too, are extremely abundant, and the guano deposited upon stems and branches where the Orchids grow must afford them far larger supplies of ammonia and other fertilisers than can be obtained from the peat and moss in which the majority of such plants are cultivated here. It may be fairly argued that we have in this no evidence that the plants are benefited by manures, for in a natural state they are often exposed to extremely adverse conditions; and if we point to the great size of pseudo-bulbs and flower stems on imported plants as compared with those subsequently produced under cultivation, it may be rightly said that the former are due to the greater sun heat and light they enjoy in their native haunts. In the absence of any definite evidence on either side, but with a presumption in favour of supplying moderate stimulants with great care, the only way of settling the difficulty was by experiments, and we have now to record some that have proved very successful.

At Higham Hill, Walthamstow, A. Borwick, Esq., has for several years had an interesting collection of Orchids which in the past year or so have made astonishing progress. Having proved the value of Jensen's fish guano for outdoor crops and miscellaneous plants, Mr. Borwick determined to try it upon his Orchids, and did so in a manner that would have been alarming to many persons. For all the Orchids in pots a compost was prepared of peat and charcoal in the usual way, but to each barrowload was added a 48-potful of the manure, which was thoroughly well mixed with the peat. The whole of the plants were then potted in this, the surface mossed over in the usual way, and they were treated in accordance with the most approved practice as regards the routine of culture. The results were so encouraging that it was decided to also try it in a liquid form, a quarter of an ounce being dissolved in each gallon of water, and being placed in the tanks in the houses it is necessarily given every time water is applied. It would not have been unreasonable, according to the ordinary opinion, to expect a great and sudden mortality amongst the Orchids as a consequence of this proceeding; but so far from this being the case the plants made a most vigorous growth, and are now as fresh, healthy, and strong as anyone could desire. Even to the least sceptical it is surprising, but "facts are stubborn things," and it is evident that manure can be employed for Orchids with considerable advantage.

Two span-roofed houses, each about 30 feet long, contain the majority of the Orchids, one being devoted to the cool species of Orchids and the other to the tropical ones. In the first, which is kept at a minimum temperature of about 50°, is an excellent collection of *Sophranitis grandiflora*, about 300 healthy plants in thumbs and 60-size pots. They were the strongest little plants we have seen for some time, and were bearing a profusion of buds, promising a beautiful display of their bright scarlet blooms a few weeks later. These, with the majority of the other plants in this house, are grown on open stages over another shelf, upon which is spread a layer of ashes kept constantly moist. Beneath this stage upon one side of the house are open tanks 4 feet deep, which receive the rain water from the whole house, and is used exclusively for the plants. *Lycaste Skinneri* is very handsome in the same house, the plants most vigorous, with stout pseudo-bulbs, while the flowers are large and of fine substance. These evidently thrive on the manure already mentioned, and there can be no question that they, with *Cypripedium insigne*, *Maxillaria grandiflora*, and several other strong-growing Orchids, have benefited considerably by the applications they have received. *Odontoglossums* of the *O. cirrhosum* and *O. Alexandræ* types are numerous and healthy, but the effects of the manure is not so marked in their case. *O. Rossi majus*,

*O. gloriosum*, and *O. tripudians* are doing well, a fine variety of the last named being now in flower. Of *O. cirrhosum* there are also some good varieties in bloom, the flowers of great size, with bold richly coloured spots. *Oncidium leucochilum* is showing a stout spike, and there are numbers of others advancing to afford a display later in the season. One plant of *Odontoglossum* deserves special notice as being one of the most distinctly variegated Orchids we have seen. The leaves are about the usual size, but are clearly striped with white, which has kept true for several years, though, owing probably to a certain weakness of constitution, like many other variegated plants, it does not grow freely—in fact, it does not seem to make any progress, but continues in the same condition. *Lapagerias* are trained to the roof of this house and are growing vigorously.

The warmer house contains a large miscellaneous collection, including some very handsome specimens of *Lælia purpurata*, *Cattleyas*, *Cymbidiums*, *Lycastes*, *Dendrobiums*, and *Ceologynes*. The last named are grand masses 2½ feet or more in diameter with large solid pseudo-bulbs, and are evidently in superb health. The beautiful Chatsworth variety is in capital condition and bearing numbers of its fine open flowers. *Cymbidium Lowianum* is represented by a wonderfully strong specimen which has ten growths this year, and six plants have been obtained from it previously. It has three spikes, one with twenty-seven flowers and the other two with twenty-four each, and one year it produced a spike with thirty-two flowers. The pot is crammed with roots, and this plant alone is ample evidence of what manure will do for strong-growing Orchids of that character. *Lycaste Skinneri* is also doing well in this house, a number of beautiful, delicately, and richly tinted varieties being included. The able gardener, Mr. Gilks, thinks that the flowers expand much better in the warmer house, the sepals and petals being straighter and more erect than in a lower temperature, where they often recurve. Of the white *Lycaste Skinneri* there are several young plants, most of which have been raised from the old back pseudo-bulbs of a purchased plant. Eight have been obtained in this way, the first growth after the old pseudo-bulbs were potted being very small, but the second growth was encouraged like the other plants, and the result is in several cases that the last season's pseudo-bulbs are larger than the original ones. Two general favourites, *Odontoglossum Cervantesi* and *O. pulchellum*, are in excellent condition, and both are flowering abundantly. The former is in small pots about 3 inches in diameter suspended from the roof, and have mostly two spikes with three and four flowers each. *O. pulchellum* is charming, growing with the freedom of *Pelargoniums*, and bearing numerous spikes of its pure white fragrant Hyacinth-like blossoms. This is one of the most useful and pretty species of *Odontoglossum* that can be grown, and if it was always seen as at Higham Hill it would soon be in greater demand than it is. A handsome specimen of *Zygopetalum crinitum* is flowering well, having three spikes of four to six flowers each, the sepals and petals mottled with green and brown, the lip white, with bands of violet hairs radiating from the centre towards the margin. These are a few of the specialities, but there were also some healthy *Dendrobiums*, *D. Wardianum* being very strong. *Anguloa uniflora* is also good, as are numerous *Masdevallias*, *Lycaste Harrisonæ*, *Oncidium ornithorhynchum*, *Cattleya citrina*, and numberless others.

A third house contains a general collection of *Cypripediums*, *Dendrobium Ainsworthi*, *Angræcums*, *Aerides*, *Phalenopses*, and other Orchids. There are a vinery and conservatory, the latter containing a miscellaneous assortment of bulbs and flowering plants, all of which, with the Vines, are assisted by the same manure as the Orchids, but in rather more liberal quantities, though even for them it is wise to err on the side of small supplies. As regards Orchids, Mr. Borwick has done good service in proving that manure can be given not only without injury, but with actual beneficial results, and though his remarks upon the subject at the Orchid Conference last May were received somewhat incredulously, his plants afford substantial evidence that his views were correct. It may be remembered that on the same occasion several other orchidists detailed their experience, and amongst them Mr. Heath stated that he had used nitrate of soda and ammonia for strewing about the houses, with the result that the colour of the foliage was greatly improved, becoming a rich green tint. Many more experiments might be made in the same way, and it is probable the Orchid culture may be revolutionised in a few years.—C.

### TRANSPLANTING CAULIFLOWERS.

THE time has now arrived when this operation may safely be proceeded with generally, though in the northern counties it will be advisable to defer doing so for a week or ten days, according to weather and condition of soil; and if the work is done as set forth below satisfactory results will be secured. A portion of the plants was pricked out singly in 3-inch pots last autumn for early spring planting, and a piece of ground has been liberally manured and trenched for this and the Pea crop. In this we draw drills, running north and south, 3 inches deep and 2 feet apart. Some plants in pots of Early London or whatever variety is grown for early work should be planted with a garden trowel, disturbing the soil and roots as little as possible in turning them out. Press the soil firmly about the balls of earth and roots. Then dust a mixture of lime and soot around the individual plants, so as to prevent slugs from interfering with them; afterwards sticking some spruce boughs firmly in the ground on either side of the plants as a protection from frosts and cutting winds.

These, after an interval of a week or ten days, should be removed from the west side of the plants to prevent their making a weakly growth, and, weather permitting, a couple of weeks later the remainder of the boughs can be removed, the plants being earthed up in due time. It will be obvious to practical readers that plants thus treated are subject to little, if any, check in the process of being transplanted, and that a few plants turned out of the pots carefully and planted about the same time at the foot of south walls and protected from the attacks of slugs, as indicated above, will yield an early supply of small useful heads. Later plantings should be made from those pricked out in pits and frames at intervals of a week or two, the plants being taken up carefully with as much soil adhering to the roots as possible, and be transplanted in the manner detailed above.

Young plants resulting from seed sown in heat the middle of last month should be pricked out 4 inches apart in boxes or in a warm border under sashes or handlights, watered, be gradually hardened off, and when large enough planted out as above described, minus the spruce boughs. Sowings of the same varieties—Early London, Walcheren, and Veitch's Autumn Giant—should be made in the open on a warm border about the middle of April, May, June, and July, and plants resulting from these sowings, if subsequently attended to as already described, will give a good supply of Cauliflowers well into the new year. In the summer the leaves should be bent over the "flowers" with a view to keeping the latter firm, as well as retarding them by protecting them from the direct rays of the sun. In early winter the same practice should be had recourse to as a protection against a few degrees of frost. I need hardly remark that during a dry summer, if good results are looked for, the plants should have liberal supplies of water given them at the roots, and it will be all the better if they are watered occasionally with liquid manure.—H. W. WARD.

#### MILDEW ON ROSE TREES.

I WISH to apologise to Mr. T. C. Clayton, and hope that he will not think me discourteous in not replying to his letter on page 70, for I overlooked his communication. I am very pleased to observe that he has altered his opinion about softsoap, and can now write favourably of its beneficial effects for the purpose for which I have frequently recommended it in your pages. I grow my Tea Roses in a heated structure from the beginning of November until the weather is sufficiently genial in spring to dispense with fire heat, when a night temperature of 55° to 60° can be insured. After this time sun heat is entirely relied upon for forcing forward the Roses if they are not coming forward as fast as we desire them. The difference, as referred to by Mr. Clayton, does not arise from the cause pointed out, for we syringe twice daily—that is, early in the morning and again in the afternoon; in fact softsoap is used whenever the trees are syringed. During winter syringing can only be done once a day, and during bad weather not so often, but at that season of the year it is always done in the morning. Mr. Clayton will thus see that no harm is caused to our Roses by the sun shining upon them after syringing, or while the foliage is wet with soapy water.

I have pointed out on several different occasions that one cause of mildew upon Roses is an injudicious system of ventilation. Cold draughts on all occasions must be avoided, as if any check is occasioned to the plants mildew is certain to appear. There are many mistaken notions respecting the ventilation of Roses when forced under glass during winter and early spring. From the hardy nature of the Rose many conclude that a liberal ventilation must be provided or the growth will be weak and the plants ruined, yet this causes them to be attacked by mildew and green fly. It is only reasonable to suppose that this would be the case when it is considered that the young tender wood and foliage is developed in a warm genial atmosphere, they are not prepared, and therefore cannot endure the cold external atmosphere. It is many degrees colder than the temperature of the house in which they are growing, causes a chill, and predisposes the plants to disease.

My advice to all who force Roses under glass during winter and early spring is to grow the plants without admitting air by means of the ventilators and doors, the latter only being opened when it is necessary to pass in and out. By this means, and through the laps of glass, sufficient air will be admitted for the proper support of the plants. I do not object to the admission of air when the atmosphere is warm and genial, and can be done without lowering the temperature of the house. Young men in charge of such structures will find this non-ventilating system much easier to be mastered and carried out than the intricate one practised in many gardens. The system of providing a circulation of air by day and night during forcing operations in winter and spring cannot be too strongly condemned, for no advantages are derived from so doing, but on the other hand the plants are checked, and thereby subjected to disease, the coal bill is increased, and the man in charge worried nearly to death by the lectures he daily receives on the mysteries of this wonderful system.

It would indeed be difficult to say why Mr. Clayton's Roses escaped the annual attack of mildew. But I should say it was escaped in his unheated house because he provided a suitable atmosphere, other conditions being also agreeable, which probably was not the case exactly in previous years. In regard to those growing outside, it is certain that all conditions

favourable to the growth and development of the Rose surrounded his plants, or they would have been attacked.—W. BARDNEY.

A DEVONSHIRE correspondent writes as follows on the LATE SPRING :—"We are still almost without a symptom of spring, and have hardly seen the sun for a fortnight. Frost again this morning (February 22nd) and everything a month behindhand. But everything comes to him who waits, and we shall no doubt be fully repaid for the cruel nipping we have had for the past two months."

— WE are informed that MESSRS. MESSENGER & Co. OF LOUGHBOROUGH have just been awarded the Gold Medal, the highest award, by the Society of Architects for the general excellence of their horticultural buildings, at the annual exhibition of the Society, which is being held this year at Sheffield.

— JUDGING by the annual report of the SOUTHAMPTON HORTICULTURAL SOCIETY affairs are not in a very flourishing condition. It appears that at the last Summer Show £100 less was received than in 1884, at the Chrysanthemum Show £70 less, and the annual subscriptions are £46 less; also 150 members have been lost and only ninety added. Still with all this the Society has a favourable balance, having received a donation of £196 from the funds of the Races Committee. This, however, is not satisfactory, and it is hoped the coming season may bring more success.

— A WELL-KNOWN gardener, MR. DAVID DOIG, OF ROSSIE PRIORY GARDENS, died recently at his house in the gardens, where he has served for the past twenty years, succeeding Mr. J. Kidd, with whom he commenced his gardening career as apprentice. He held several head situations before being appointed gardener at Rossie Priory, and was noted as a skilful horticulturist and for his knowledge of British plants.

— THE YORK FLORAL FETE is fixed for June 23rd, 24th, and 25th, and is to be held, as usual, in the Bootham Field. Ninety-six classes are provided in the schedule, the prizes being of the customary value, from £20 to 3s.

— MR. JOHN BURN, Felton, Northumberland, writes :—"Can any of your readers tell me how to prevent CATERPILLARS EATING FRUIT TREE BLOSSOMS inside orchard house? as last year I had some Apple blossoms totally destroyed, and they were so thick I could not get at the caterpillars with my fingers."

— THE ROSE SHOW AT MORETON-IN-THE-MARSH will be held on July 13th. Good prizes will be offered, and as the Society is affiliated to the National Rose Society, and the Revs. F. Burnside and J. W. Clarke are Secretaries, there is every prospect of a successful exhibition. Many rosarians will be sorry to hear that there is not to be a Rose show at Darlington this year.

— AN Orchid grower sends the following note, entitled A BLUE ORCHID : "It appears that an important addition has been made to the few blue-tinted Orchids we possess, for in the recent issue of one of your contemporaries, in a paragraph describing Mr. Philbrick's Orchids, it is remarked that 'Odontoglossum pulchellum, of sky-blue colour, and finely scented, was found in abundance, on one plant eighteen spikes were counted.' Is it possible that 'a sky blue' variety of this pure white Odontoglossum can have been obtained by Mr. Philbrick? If so it will be valuable; or could the writer have mistaken white for blue?"

— AT a recent ordinary meeting of the members of the WAKEFIELD PAXTON SOCIETY, Mr. T. Senior, the President, was in the chair, and Councillor Milnes occupied the vice-chair. According to the syllabus, Mr. E. B. Wigglesworth, one of the collectors in the waterworks department of the Corporation, should have read a paper on "Properties and Causes of Scent," but as he was unable to fulfil his engagement Mr. Herbert Chapman, the Honorary Secretary, read a paper by the Rev. Canon Hole on "The Happiness of a Garden." A vote of thanks was given to Mr. J. B. Charlesworth, J.P., of Hatfield Hall, for a gift of a

number of volumes of the *Journal of Horticulture* to the Society's library. Mr. T. Garnett, one of the members of the Society who attended the annual dinner of the Barnsley Paxton Society on the previous Tuesday evening, gave a report of the proceedings, from which it seemed that they were of a very encouraging and satisfactory character.

— A PAPER on "INSECTIVOROUS PLANTS" was recently read before the Wakefield Naturalists' Society, by Mr. P. F. Lee of Dewsbury. There was a good attendance. Mr. G. Parkin presided. Mr. Lee mentioned a number of plants, both British and foreign, which possess the animal-like attribute of utilising organic matter as food, as an aid to the ordinary method of vegetable nutrition, and then explained how this peculiar process is carried on. He pointed out how the plant captured its living food, and how by means of glandular secretions a process of digestion was set up in a manner singularly analogous to that which characterises animal life. A discussion ensued in which Messrs. Spurling, Garnett, and Fallas took part, and a vote of thanks was given to Mr. Lee for his paper.

— "H. S. O." sends us some handsome blooms of *DENDROBIUM WARDIANUM*, large, highly coloured, and borne in triplets. He also sends blooms of *Cattleya Trianae* and the beautiful *C. Warscewiczii delicata*, all showing excellent culture. Remarking upon the treatment of the *Dendrobium* our correspondent writes as follows:—"We have here about sixty plants and divide them into four batches. They give us a constant succession of bloom for four months—viz., from the beginning of the year until the end of April. They receive plenty of heat and moisture while growing, and a good season of rest. When growth is finished they are removed to the vineries and hang there until the flower buds are prominent, and during this time very little water is needed. They can then be brought into bloom as required by taking them back to warmer quarters. If thought desirable, the blooming period may be prolonged by removing them to a cooler and drier house as soon as the blooms are well open, but if the young growths are somewhat advanced this treatment does not benefit the plants."

— ROYAL AQUARIUM, WESTMINSTER.—The Directors of the Royal Aquarium have accepted a scheme submitted by Mr. Richard Dean of Ealing for a series of four horticultural exhibitions to take place during the coming season—viz., a display of Hyacinths, Tulips, &c., and cut Daffodils on Tuesday, March 30th, and Wednesday, March 31st; a great artistic Rose exhibition on Friday, June 25th, and Saturday, June 26th; a Strawberry fête and exhibition on Friday, July 2nd, and Saturday, July 3rd; and a great display of table decorations, bouquets, &c., on Friday, August 20th, and Saturday, August 21st. Liberal prizes are offered, and schedules of prizes can be obtained of Mr. Richard Dean, Ranelagh Road, Ealing, the Superintendent of the shows.

— It is not often any new designs in GARDEN RAKES are advanced; the Rev. J. Harding Cole, Woodview, Co. Cork, has, however, introduced a rake that is quite new. The inventor has found this implement extremely useful, and we doubt not it will be found equally serviceable by others, both gardeners and amateurs. The sample before us is strong and well made. The rake is described in the prospectus as follows:—"In using the rake on gravel walks, there is always experienced a want of something with which to extract or remove anything which the teeth of the rake will not catch, such as growing weeds. This important desideratum is now supplied by the 'Weeding and Hoeing Rake,' in which each extreme tooth forms a chisel-shaped steel cutter or grubber, capable of eradicating any weeds with facility and without injury to the implement. To give better effect to these cutters a curve is given to the back of the rake. These improvements largely extend the utility of the implement, not only in raking gravel walks, but also in many gardening operations, such as weeding, hoeing, opening drills for seeds, and thinning. As a hoe it is an extremely useful and handy garden tool, by reason of its narrowness, for working between plants, loosening the soil, &c., and the penetrating power afforded by its shape, at the same time, collecting the weeds as a rake, thus doing the work of two implements together."

— THE current issue of the "Botanical Magazine" gives coloured plates of the following plants—T. 6858 represents a bold handsome Orchid, *LISSOCHILUS SAUNDERSONI*, but which is little known in this country. It is described as "a native of Natal, and was first made known by a drawing sent to Kew by the late Mr. Saunderson in 1867, from which Reichenbach's specific description was drawn up. . .

*L. Saundersoni* of Harvey is quite a different plant, referable to the genus *Cymbidium*. For plants of this majestic Orchid, the Royal Gardens, Kew, are indebted to Mr. Lyle of Natal, who gave them in 1879." It produces fine lanceolate arching leaves, 3 or 4 feet long, and 3 to 4 inches broad. The scape is 6 or 7 feet long, bearing the flowers on a foot length from the apex, and they somewhat resemble the larger *Zygopetalums* in general form. The sepals are greenish, the petals broad and white, and the lip purple with darker veins.

— IN t. 6859 is given a figure of *CALOTROPIS PROCERA*, an Asclepiad, which inhabits western and central India, "where it is known for its medicinal properties as Mudar. . . . The inner bark yields a strong flax, from which halters, lines, and ropes are made; the silky hairs are used to stuff mattresses; the acrid milky juice, mixed with salt, is employed to remove hair from hides. Pieces of the roots are in common use for tooth-brushes, and gunpowder charcoal is made of the wood." The drug "Mudar" is prepared from the bark of root, stem, and branches, and is used as a tonic, a substitute for ipecacuanha. The flowers are nearly an inch in diameter, white on the outer surface, purple at the upper half of the lobes, and white at the base. They are borne freely in umbels from the axils of the leaves, which are elliptical and bright green. It forms a shrub 6 to 10 feet high.

— THE two following plates, t. 6860 and t. 6861, are devoted to *Synthyris reniformis*, a Californian plant with long racemes of small pale violet flowers and reniform leaves; and to *Rhynchanthus longiflorus*, a Zingiberaceous plant of little beauty, but interesting botanically. *CALOTROPIS GIGANTEA* is shown in t. 6862; it is a near relative of *C. procera* already noted, but is much stronger in habit. The flowers are more curious and less attractive. It is applied to nearly the same uses as *C. procera*, but "the strong silky flax yielded by the inner bark of *C. gigantea* is finer, and used for making the robes of native princes, as also for bow-strings, fishing lines and nets, for which latter purpose its indestructibility in water recommends it."

— LIKE Mr. G. A. Sala and other visitors to the metropolis of New South Wales, Mr. J. E. Taylor, Editor of *Science Gossip*, seems to have become quite enamoured of the SYDNEY BOTANICAL GARDENS. He says—"There are many trees of special note growing in the grounds, the principal of which, perhaps, is a magnificent Norfolk Island Pine (*Araucaria excelsa*)—a tree very abundant in the larger gardens and shrubberies of nearly all Australian towns. There are also fine specimens of the well-known Australian proteaceous plant, *Grevillea robusta*—perhaps the largest and most attractive of this singular order. *Merytas*, with their broad and showy foliage, the Maidenhair-leaved *Salisburya* from Japan (a coniferous tree, which has been in existence ever since the carboniferous period), the singular Manitian Palm, the Bloodwood of Norfolk Island (*Baloghia lucida*), the Osage Orange of America (*Maclura aurantiaca*), the Moreton Bay Chestnut (*Castanospermum australe*) with its deep green foliage and bright scarlet flowers, the Tulip-woods of Eastern Australia (*Harpallia pendula*), the *Randia macrophylla* from Lord Howe Island, besides Bananas, Bamboos, multitudes of species of Palms, New Zealand Cabbage Trees, *Dombiyas*, *Pterospermas*, *Nepheliums* from China, *Eleocarpus* from India, *Brexiars* from Madagascar, *Lactarias* from the Queensland bush, Sacred and other Fig trees from India, *Sciadophyllums* from New Guinea, *Botryodendron* from Norfolk Island, Cycads and *Zamias*, *Strelitzias* from the Cape, a vast number of species of Pines, *Erythrinars* from the West Indies (just bursting into their singular scarlet blossom), and many others too numerous but not too unimportant to mention unless in a botanical inventory—make up the diversified and wonderfully combined arboreal foliage with which the diversified surface of these beautiful gardens is clothed. Floral parterres and patches are gay with flowers whose manifold colours offer a rich feast to the eye. The rocks and rocky places are covered with the grotesque forms of Cactuses and Aloes. Climbing plants from all parts of the world have been trained to clamber up and festoon trees and shrubs of a less conspicuous character. All that botanical and horticultural art and skill can do, combined with perhaps the most picturesque situation in the world and a most delightful climate, have made the Sydney Gardens a place worth coming to the antipodes to see.

#### PALMS AND OTHER PLANTS FOR INDOOR DECORATION.

I CAN strongly recommend "A Thinker's" advice (page 132) to grow *Kentias* for the above work. We have two plants nearly 10 feet high in 12-inch pots that have done an immense amount of work. They have

stood in the entrance hall six weeks at a stretch in the autumn. Occasionally they have been used for dinner table and drawing-room decoration, done useful service at harvest and other festivals, and a year or two ago went up to London for the season. With all their hardships they always wear that cheerful deep green hue that "A. T." alludes to. When at home they stand in the shadiest corner of the stove, and a dose of a mixture of soft soap and petroleum keeps them clean.

When rooms, entrances, and passages of a mansion are required to be decorated six months of the year it is useless to rely on tender subjects, but plants of a lasting as well as of a bold and effective character should be grown. I place Palms first as the best decorative plants, especially *Kentia Belmoreana* and *Phoenix rupicola*. *Curculigo recurvata* is very good, also *Ficus elastica* with single or three or four stems. *Acalypha Macafeana* is a fine distinct plant with large bright-coloured foliage, which lasts a long time in a warm room, a good quality which cannot be said of *A. musaica*. *Oreopanax nymphæfolia* is one of the plants that cannot be killed. As its specific name implies, it has large glossy leaves. *Anthurium crystallinum* is all for brackets or where a one-sided plant is wanted. *Cupressus funebris* in its young state is a capital plant of a columnar habit and very pleasing shade of green. The list could be lengthened, but these will give an idea of what I mean. We do not use the conventional *Dracenas*, they remind one too much of the conserved plants you can buy at so much per yard.—DALESMAN.

### LIME FOR VINE BORDERS—ANALYSIS OF SOIL.

I WAS sorry to see Mr. Bardney's name attached to such an article as that on page 104. Discussion may improve all concerned, personalities never. If my motive for writing had been what Mr. Bardney insinuates, which I deny, it matters little so that the information is correct; and if he can supply any hints likely to prove useful in the study of qualitative analysis, many, no doubt, would be grateful, whether given to air his knowledge or for the public good. My impression on reading his first article was that many people, amateurs especially, would be led into a reckless use of lime not to be counselled.

Because a kitchen garden poisoned with manure is improved by a heavy dressing of caustic lime, does not prove it to be advisable to apply lime in that state to Vine borders, and in such a quantity as to whiten the soil. I believe such a quantity of lime in a new border would cause the rapid decay of all vegetable matter, and a large amount of the fertilising matter set free would be washed away. If I were called upon to construct a Vine border with turf cut from a sandstone formation, instead of giving lime in the form of powdered carbonate of calcium, or what would soon assume that form—slaked lime, and so destroy the turf, I would use phosphate of calcium in the form of bones, whole, or nearly so, which would preserve the turf as long as possible, and yield a supply of lime for many years. Nitrogen and potash could be given as a liquid. I may mention that fresh bones are the best, as they will yield much nitrogenous food.

If slaked lime is applied it would be better as a top-dressing, but not in the way Mr. Bardney advises. If lime is mixed with partially decayed or readily soluble substances containing ammonia, the ammonia would be liberated and escape into the air, as anyone may prove by dissolving a handful of sulphate of ammonia or guano in a little water, and then mix a handful of lime with it. It would be better to give the lime first, and wash it in before applying the compost. Mr. Bardney says, "Vine borders dressed annually with manure contain much humus;" again I differ from him. After having a year's washing, and all the readily soluble constituents taken from it, most of the remains are raked off, so that there is little humus left, and the value of lime in a Vine border should be chiefly that of a manure, and not as a solvent of inert matter. Respecting the kitchen garden, of course the cost of phosphate of calcium in any form would prevent its use except in special case.

Ordinary lime is easily procurable and cheap, but it is liable to be overdone, and so set at liberty more food than is necessary, which will be washed into the subsoil and drains and be lost. I should consider eighty to a hundred bushels a good dressing, but it should not be buried deeply. The ground should have been dug first and the lime pricked in, as lime has a natural tendency to sink, and care should always be taken when applying manure to dig it in before putting on the lime, that no ammonia be lost. As an after dressing about fifteen bushels every alternate year would be enough, and likely to produce good results, and would save much manure, lime, and labour.

Where chalk is procurable I should prefer it to caustic lime, as its action, though similar, is milder and lasts much longer.

Since writing the above I have seen "Thinker's" statement. Does he apply his lime, not like Mr. Bardney, or is it exposed to the air a week before digging it in?—A. L. G.

### SOWING WRINKLED PEAS EARLY.

AT page 109 your correspondent "Lathyrus" tells your readers I am in error in Pea culture. Not ten yards from where I am writing I have a border of early Peas now just breaking the ground. They are all round seeds except one, and this is Early Bird (Burbury's). The whole have come up well except that, of which there are not ten peas up in each row, and the variety is the only one with wrinkled seed. I have yet to learn that half a pint of several new or recent varieties produce an equal crop to more than a quart of some fairly good varieties. Having grown the majority of the new Peas that have been sent out during the last twenty years, I can now confidently assert that no Pea of recent

introduction, either for colour, produce, or flavour, can equal the three following—Standard, G. F. Wilson, or Omega, all of which have been before the public for at least ten years.—KITCHENER.

### MILDEW.

I WAS pleased to read on page 88 that "H. C. W." had proved the value of lime and sulphur as a preventive of mildew; I have been successful with it, but the strength I use it differs from his.

We have a *Maréchal Niel* Rose trained to the roof of a greenhouse which was very subject to the disease, but after a few applications at the strength given below, the only traces of mildew were the black patches in the leaves where they had been attacked before. I have not had time to practise much with it in the open air, but under glass in the vineries, orchard house, and amongst Roses I have used it with the most beneficial results. The quantity I make is 2 lbs. of flowers of sulphur, 2 lbs. of unslaked lime, adding ten quarts of rain water, boiling it twenty minutes, well stirring it all the time; let it stand till cold, then bottle and cork down, using at the rate of one wineglassful to three gallons of water. It is necessary to attend well to the stirring process while boiling, otherwise the sulphur will not mix with the lime and water, and as "H. C. W." observes, should be used in the evening. If the first application does not destroy, it should be repeated occasionally, until it has the desired effect.

When used in the houses the mixture always discolours the paint and woodwork where it touches, and unless syringed off with clear water whilst fresh, will require scrubbing off afterwards.—G. W. CUMMINS.

### A GARDENING TOUR.

MANY horticulturists were attracted by business or pleasure to the great Exhibition at Antwerp last year, and a number of these visitors like myself took advantage of the opportunity thus afforded, and extended their journey to the principal towns of horticultural importance in Belgium. There was a time when such a trip would have been regarded as a considerable undertaking; but there are now so many routes by which the Continent can be reached, the service of steamers is so good, the passage so quick, and the fare so moderate, that a journey thither is looked upon as an ordinary occurrence, and is a part of many persons' common business routine. Still, to the young Britisher who first crosses the ocean there is much novelty and interest even in a visit to such near neighbours as the Belgians, which is rendered still more enjoyable by the friendly welcome all concerned in gardening are certain to receive. Nor can an observing man spend a week or so there without gaining some useful additions to his knowledge, for though we can see few private gardens kept in the style we are accustomed to in our own little island, yet commercial gardening is carried out on a most extensive and economical scale. Rapidity of propagation and quick growth are the prevailing rules at these very numerous establishments, and it may be safely said that many a useful lesson has been learnt in them by home nurserymen. Indeed a period spent in such continental "factories" is considered as an indispensable portion of the education of our rising young nurserymen. In other respects some advantages result from a visit to our neighbours, for a stranger cannot be in the country long without being impressed with the business aptitude, the industry, and the commercial solidity of the people; there is also an enthusiasm in most undertakings which is quite refreshing after the phlegmatic way in which we conduct affairs. This is well seen in the numerous societies, meetings, and exhibitions, the latter being substantially supported by both Government and townsfolk, and invested with an importance that they never seem to have in this country. Horticulture is regarded as one of the leading industries, and in consequence holds a high position amongst the trades and professions. That it pays for the encouragement it receives is evident from the enormous business in plants transacted not only with Great Britain, but with America, France, and Germany. The country seems to be a great nursery for the Continent generally, and it would be difficult to estimate the amount of exports to the principal countries. Azaleas and Palms, however, certainly run into millions, and one firm alone grows at least a million Palms, while acres of Azaleas can be seen planted out. These are only items in the trade, but give an idea of what horticulture is in Belgium. It has however been repeatedly described, and the older readers of this Journal are familiar with numerous instructive and entertaining articles from an able writer. I can therefore only advise them to pass the following rambling notes, which are written for the new readers or non-travellers who have not had an opportunity of inspecting continental gardens and nurseries. My programme may serve as a guide to those who are meditating a similar tour during the coming spring or summer, and for their benefit my jottings will not be exclusively technical.

### ANTWERP.

Steaming slowly up the "lazy S. heldt," as Goldsmith termed it, we sighted the cathedral tower of Antwerp late in the evening of a brilliant summer's day. We had a delightful passage from Harwich in one of the Great Eastern Railway Company's commodious vessels, and it was almost with a feeling of regret that the very uninteresting river was entered. It was the first day passage of the season, and, except where economy of time is an object, I should greatly prefer this mode of crossing the German Ocean, for in fine weather nothing could be more enjoyable. Some friends who feared the *mal de mer* selected the shorter sea routes, but they are not always the least troublesome in that respect, and if Antwerp is the destination it necessitates a long train journey after landing. The Great

Eastern Railway steamers run alongside the quays in the town and within a convenient walk of the principal hotels, several of which, such as the Hotel de l'Europe and Hotel St. Antoine, are situated in the Place Verte, which is easily reached from the quays. For those who wish to be more economical there are numbers of smaller quieter hotels farther up in the town, where the charges are very moderate, the accommodation good, and where English is spoken, an advantage which many will duly appreciate. A moderate knowledge of French is a valuable assistance in a journey to Belgium; it will smooth many difficulties and facilitate travelling, but it is not essential, for there are thousands of English-speaking people in the towns, and a question in good plain English is often more likely to bring a satisfactory answer than a lame attempt to express one's wishes in French. It is surprising what a number of persons are met with who can transact their business in four languages. First there is the Flemish, the native dialect of the country, something akin to the Dutch, with many words identical with or very similar to our own. Then there is the French, the polite language, which is written and printed and generally used in conversation, except in a few places and out of the towns. Third

Fig. 26.—*Rhododendron hirsutum*.

and fourth are English and German, which are the business languages, and with which many are familiar in such centres as Antwerp. At most of the railway stations the clerks can speak a little English, and at many of the principal stations directions as to ticket offices, trains, &c., are posted up in three languages—French, Flemish, and English. Everything, in fact, is done for the convenience of travellers and to encourage visitors, and an instance of this was afforded at the time of the Exhibition in Antwerp. For the benefit of strangers an official register of respectable lodgings to let in the town was formed. They were inspected and classified in certain grades, according to the accommodation provided and their respective charges. A friend who availed himself of this obtained very comfortable apartments and excellent attendance at more moderate charges than he could have done at the hotels, where the prices rise alarmingly on special occasions.

These notes by the way; but my object in Antwerp was to see what was horticulturally interesting, and then the features of general importance, and in both I was greatly assisted by an excellent friend, M. Charles Van Geert, to whom I shall ever consider myself indebted. Under his guidance more was accomplished in a couple of days than would probably have been otherwise seen in a week, and the pleasure was further increased by the agreeable manner in which it was performed. Antwerp is interesting in several ways. Its rapid extension in recent

years, the fine dock accommodation and wonderful quays afford ample evidence of a most cheering present and future prosperity, while the old portion of the town, with the numerous ancient buildings of quaint architecture, and its grand old cathedral, are indications of a long, chequered, past career. It is also by no means wanting in beauty, though its "Places," "Avenues," &c., cannot be compared with those of Brussels. They are spacious, well planted with trees, and in the summer form pleasant shaded promenades such as we often sigh for in London. There is a pretty park of moderate extent, well kept, and bright with flowers, many of the open spaces being similarly enlivened by beds of flowers and fresh green turf. The museums and picture galleries furnish numerous attractions, and one, the Musée Plantin, should be visited by all, for it is one of the most interesting in the town. It was for a long time in the possession of a family who there printed and bound a great number of books upon all subjects, including some of the oldest botanical works, such as those of Lobel, Dodonæus, Clusius, and others. The engraving and every detail, even the type founding, was done upon the premises, and the old instruments, blocks, and proofs are still shown. At the time the members of the Botanical Congress visited the Museum a sheet of hand-made paper was printed from the old type with blocks from the works of the botanical authors named, and presented to the visitors as a memento.

With the exception of M. Charles Van Geert's nursery and two or three private establishments, there is not much of horticultural importance in or around Antwerp, but by a short journey the wonderful nursery at Calmpthout is reached, and nearer still is one of the most interesting and best kept gardens in Belgium, to which a few notes must be now devoted.

#### A BELGIAN AMATEUR'S GARDEN.

A few miles from Antwerp on the Brussels line is a village bearing the curious title Vieux-Dieu, and a short distance from the station is situated the garden and residence of M. Jean Everaerts, one of the most celebrated amateur horticulturists in Belgium. The garden is in many respects a remarkable one, and presents a most agreeable surprise to those who have visited a few of the private establishments in that country. The surroundings are not picturesque, being somewhat flat, like the greater portion of the district round Antwerp. The soil would have been sufficient to discourage the most ardent enthusiast, being shallow, in many places very sandy, and in dry weather quite loose and dust-like. Directly the garden is entered, however, it seems as if we have passed into another country, for we see abundance of fine trees, varied shrubberies, velvety lawns, and a diversified surface such as could never have been expected. It is not the production of a few months, but represents years of steady improvement under the superintendence of the owner and his equally enthusiastic wife. When amateurs take a genuine interest in their gardens they perform their work in a manner that would do credit to many professional gardeners, and the best results are obtained by those who have a love for their occupation. So it is at Vieux-Dieu. M. Everaerts has had innumerable difficulties to encounter, but perseverance and an increasing interest in the work has enabled him to overcome them, and he has now every reason to be proud of the result.

The garden comprises about 33 acres, devoted to flower garden, kitchen garden, plantations, lawns, and rockery, which are enclosed by walls or wire netting as a protection from the rabbits, which are far too abundant for the safety of garden occupants. Two or three houses are devoted to Vines and greenhouse plants, Zonal Pelargoniums and Carnations being specialties, groups of both these being exhibited at the leading shows with much success, and the Souvenir de la Malmaison Carnations are admirably grown. But it is out of doors we find the great attractions of the establishment. One of the first which takes attention is a handsome flower border over 6 feet wide, which encircles a lawn and shrubbery of 5 acres. This is planted with a choice and extensive collection of herbaceous perennials, bulbs, &c., all the most effective that could be obtained from this country or elsewhere being included, and a most valuable supply of flowers it affords throughout the greater portion of the year. It gives very little trouble beyond occasional weeding when required and an annual winter-dressing of manure in December. The plants are encouraged to grow strongly and naturally, the object being to avoid the formality so often apparent in gardens. A winding walk passes through the shrubberies, and near it is a border of Pinks that afford flowers by basketfuls, and are much valued for the sweetness and unassuming beauty; indeed, all old garden favourites are valued there. M. Everaerts finds it a good plan to lift and replant the Pinks every three years, and, judging by the strong healthy clumps, his system suits them admirably. In prominent positions around the shrubberies bulbs have been planted by thousands, such as Tulips, Crocuses, Hyacinths, and Daffodils. There they are left all the year, and with the exception of the annual dressing like that given to the herbaceous border they receive but little attention. In the early spring months they render the garden very gay with their brightly coloured flowers, and no better time could be chosen for a visit to Vieux-Dieu than March or April in favourable seasons. This method of planting bulbs is more practised than it was a few years since, but even now there is plenty of room for the production of charming effects in gardens to precede the summer floral display.

From what has been said respecting the soil it would scarcely be expected to be a favourable situation for trees and shrubs, particularly Conifers, yet there is an excellent collection, comprising the best of the deciduous and evergreen species, while the Conifers include a number of handsome vigorous specimens. Retinosporas seem to be especially well suited and are thriving capitally. Several species of Abies are similarly good, and a specimen of *A. Hookeriana* 9 feet high, beautiful proportioned,

is one of the two best examples of this handsome Conifer in Belgium, the other being in M. C. Van Geert's nursery. *Cryptomeria japonica* also grows vigorously, a finely shaped tree 25 feet high being very notable. *Abies Nordmanniana* is represented by some beautiful specimens, but *Wellingtonia* and *Araucarias* which had previously done well were killed in the winters of 1879-80 and 1880-81; young plants have however been placed out, and at present seem to be progressing favourably. Roses occupy considerable space, and a number of medals from various shows prove with what success they are grown. They are great favourites with Madame Everaerts, and receive her special attention.

Returning from the shrubberies we approach a small lake, and skirting this is a path with a rustic fence, leading to the most remarkable feature of the garden—the rockery. Without rivalling the York Rockery for extent, this is in some respects an extraordinary production, more especially as being the work of one person, and its history may be briefly given in M. Everaert's own words. "It was commenced twenty years ago, was very modestly and gradually enlarged by continual personal work during leisure hours, business retaining me in town from 9 A.M. to 5 and 6 P.M.

display is made in the spring, April being one of the gayest months, for at that time a large number of early-flowering plants are at their best. *Aubrietias*, principally *A. græca*, occupy much space; the rich blue *Lithospermum prostratum* scrambles about over the stones in all directions. *Saxifraga oppositifolia* and others flower abundantly early in the year. *Silene acaulis* and *S. alpestris* furnish some lovely tints of pink, while *Veronicas rupestris* and saxatiles supply blue tints. *Primulas* of many species and varieties, the delicate little *Soldanellas* with their charming fringed flowers, *Linaria alpina*, and *Daphne cneorum* are all conspicuous for their numbers. The humble namesake of a great botanist, *Linnaea borealis*, is thoroughly at home, creeping in all directions over the stones; while that difficult plant the *Edelweiss* could not be better in its native home. A few *Rhododendrons* are employed, and amongst these are extensive patches of *Saponarias*, which also hang over the larger rocks, clothing them most gracefully. *Omphalodes* and *Forget-me-nots* are abundant and strong, but one of the most telling features is *Erinus alpinus*, which is thoroughly established, seeding freely and flourishing in all parts of the rockery. A pretty dwarf shrub which succeeds well in the rockery

Fig. 27.—ROCKERY IN M. J. EVERAERT'S GARDEN AT VIEUX-DIEU, BELGIUM.

Every stone has been placed with my own hands, and every alpine has been planted by myself." Moreover, a large proportion of the occupants have been collected in the Swiss Alps by M. and Madame Everaerts, and established in their present quarters after much care and some unavoidable failures. Comment upon this is needless; it has been a work of love, and the results are unequalled. A mound was raised artificially to the height of 25 feet above the ground level, declining at some parts to 20 feet, and then sloping down into lower ranges and mounds, forming little valleys and suitable nooks for alpine plants of all requirements. The total length with the outlying mounds is over 100 yards, and it is traversed by narrow winding walks into rough natural stone steps. The stone is employed in large irregular blocks and arranged as informally as possible, like the numerous alpine scenes the designer has seen. To introduce an element of utility, however, the lower portion of the rockery is occupied by an ice cellar. In the engraving (fig. 27), which has been reduced from a photograph, a portion of the rockery slope is shown at its highest part with the lake at the base, but it is difficult to do justice to it in this form, though it will suffice to illustrate the general plan.

It would be impossible to enumerate in these notes the whole, or even the most beautiful, of the plants which occupy the rockery, and a few observations upon the principal features must suffice. The great

is *Rhododendron hirsutum* (fig. 26) or the Mountain Rose, as it is sometimes termed. With *R. ferrugineum*, *album*, and a few dwarf Himalayan species it grows and flowers profusely. *Andromedas*, *Pernettyas*, and *Ericas* are employed in the most exposed positions, while in the shady parts *Gaultheria procumbens luxuriates*.

*Cypripediums*, such as *C. Calceolus* and *C. spectabile*, appear to be equally happy, but the latter is seldom seen in such fine condition, for some plants last year bore between fifty and sixty richly coloured flowers. *Lilium auratum* thrives and gains strength yearly, all the protection that is given being an old door placed over the bulbs to throw off the rain, which does them more injury than the frost. Bulbs are planted freely, as in part of the shrubbery already mentioned, and yield their flowers in profusion, as also do the *Hellebores*, of which there is a good collection. These last named have been very fine this season, the old Christmas Rose having flowered grandly. *Sedums* and *Sempervivums* serve to clothe many of the rocks, and in the lower portions a collection of bog plants, such as the Buck Bean, *Pontederias*, &c., *Water Lilies* having a place at the margin of the lake.

Such is a brief list of the plants which M. Everaerts has been successful with, and that have rendered his rockery so famous. But he says, "I have of course had many failures and even till now have not succeeded

in acclimatising the *Androsaces*, the *Pinguiculas*, the *Azalea procumbens*, *Gentiana bavarica* and *verna*, and that prettiest of all alpine gems *Eritrichium nanum*, which is found on hard gritty ledges of high mountains, where melting snow from above gently percolates through the hard stony soil. These gems seem to grow well enough, but are eaten, uprooted, or otherwise tormented and destroyed by snails, moles, crickets, and black-birds, the latter uprooting the plants in search of some earthworm attracted during hot summer days by the moisture of the roots. I have saved some *Androsaces* and *Gentians* lately by protecting them from the marauders by pieces of wire netting. We wage continual war against the mole, crickets, pouring oil into their little galleries, which soon brings them to the surface and causes their death." With these few exceptions the success has been surprising, and M. Everaerts deserves all the praise due to a skilful horticulturist.

The kitchen and fruit garden departments are well attended to by a gardener, who, by the way, has, through the liberality of his employer, learnt English that he might read the *Journal of Horticulture*. In every department, however, the proprietor superintends, and right well is the work performed. My visit was a brief one, but never have I spent a more enjoyable hour than in the garden at Vieux-Dieu.—LEWIS CASTLE.

## THE ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW.

### PRIZES FOR GARDEN PRODUCE.

THE date at which the Royal Horticultural Show at Liverpool has been fixed surprised me, and I think it would have been decidedly better towards the end of July or early in August. This date, the 29th of June, will certainly exclude nearly all vegetable growers from the northern parts of the country; in fact, they will be entirely shut out—that is, if the schedule contains prizes for vegetables. It is too early to expect a good display of fruit. No doubt, Black Hamburg Grapes, Peaches and Nectarines, Melons and Strawberries, may be gathered together in quantity, but a good representative fruit and vegetable show can scarcely be expected. Although the date is too early for the above, it will be right for a good display of Roses and Orchids, which will be more plentiful in June than in August.

I was, however, going to write about the excellent suggestion of "Ex-exhibitor," and not to criticise the date at which the Royal Horticultural Society have fixed their Show to be held in Liverpool. The system of grouping small decorative plants has become a general one, and very effective and interesting they certainly are, in fact few exhibits are more admired by the public. I think the "Royal" would be doing a service to horticulture generally if they took up the idea of "Ex-Exhibitor" and offered substantial prizes for a miscellaneous collection of garden produce, or as stated on page 128 "everything that a gardener can arrange as representing his work and practice. If the Royal did this they would be taking a new departure—for the notion is new as far as I know—and add materially to the interest of the exhibition. Not only so, but they would be setting a worthy example, which would be taken up and carried out in the future by other societies, horticulture would be more widely and generally stimulated than is the case by exhibitions as conducted at the present time. I do not doubt that if the officials of the "Royal" think this suggestion worthy of their consideration that the class provided would be worthily represented. Now that the shows are going to be held again in the provinces some new departure should be taken or distinctive feature displayed to render it in advance of those that have been previously held. The "Royal Horticultural Society" has been "sleeping" lately said a friend the other day, and I believe gardeners and horticulturists generally are anxious and desirous to see it again the leading spirit and prime mover in horticultural matters. I support "Ex-Exhibitor's" suggestion, and I do not see that anything can be added to it, except that similar provision be made for nurserymen and seedsmen. Such an assortment that could be provided by them could not fail to be interesting and attractive as well as instructive to all lovers of horticulture.

### PRIZES FOR GARDENS.

Prizes are given for farms, why could not the Royal Horticultural Society offer a cup, medal, or substantial money prize for the best kept garden within a certain radius of the exhibition? When I write the best kept garden, I do not mean the largest and most extensive, but the quality of the whole produce of the place might be subjected to the judgment of those appointed for the purpose. The whole contents of the houses, whether plants or fruits, the vegetables, the flower and fruit garden as well as the general condition might be considered. The object of the Royal Horticultural Society is to advance horticulture and stimulate horticulturists to zeal and energy, and would not some suggestion such as this assist in carrying out the object in view? By so doing I am inclined to think the Society would rise considerably in the estimation of that class who would otherwise be excluded from taking an active part in making an attractive exhibition in the Botanic Gardens. There are many employers who object to their gardeners exhibiting, but very few indeed would, I think, object to the produce of their garden being subjected to the judgment of competent men. They could not well object, for in the end they would be the gainers, for those in charge would certainly exert themselves to the utmost to excel with all they took in hand, whether fruits, vegetables, or flowers. This is no new notion, for it has been practised by some societies on a limited scale, principally for cottage gardens, and in others as far as lawns and flower gardens are concerned. There would certainly be some difficulties in the carrying out of this project,

but there are difficulties in every undertaking, and surely these could be surmounted. They are in the case of the farm, why not for the garden?

### PRIZES FOR BOILERS.

There have been many discussions from time to time on the relative merits of boilers for horticultural purposes. There has not been a boiler contest since the one held at Birmingham—if my memory serves me right—and would not the exhibition to be held be a fitting opportunity for testing the merits of the various boilers in the market? Liverpool is very central, and in my opinion no branch of horticulture—for such it may be termed—is of greater importance or more deserving the attention of all interested in gardening pursuits. We cannot well do without a boiler of some description to heat our plant and fruit houses, and when new ones are required it would be a great advantage to know which could be relied upon as the most durable, economical, and by which the desired heat could be achieved in the least possible time. Many boilers, although they may be durable, are neither economical nor can they be heated quickly. One that can be heated quickly and at the same time effect a saving in fuel, combined with durability, is the boiler that is in request at the present time. I believe there are boilers which combine all these qualities, but it would be well to know which they are or the one considered the best by the authority of the Royal Horticultural Society. I think if those who have the management of the Exhibition in question could see their way to arrange a contest, and thus settle this question for the present, they would be doing good service, which, I believe, would meet with the approval of hot-water engineers as well as gardeners. I know several of the former as well as the latter who are anxious that a boiler contest should take place, and it is certain that if this matter cannot be entered into by the "Royal" this year it will not be long before it engages the attention of some of the leading provincial societies.

I do not well remember the conditions upon which the boilers contested at Birmingham, but throw out the following suggestion for the consideration of all who may be interested in this subject. I think the best plan would be to provide each competitor with a certain quantity of coal and as much water as would be equal to 1500 or 2000 feet of 4-inch piping. At a certain distance from the boilers as might be arranged the water, except that required for the boiler and connecting pipes, should be in a tank. Those who heated the water in the tank to any heat that might be specified in the least time and with the smallest quantity of fuel should be accorded the premier position, provided the durability of the boiler was considered equal, if not superior to the others, or was at the least perfectly satisfactory in this respect. The thickness of the iron of which the boiler was made, whether cast, rivetted, or welded, should also be considered in judging, for one with a very thin plate of iron would certainly heat first, but would lack durability. I do not think the contest should be decided by one trial, but that they should be tested for three or four consecutive days, or each day during the time the exhibition is held.

I hope that these few ideas may draw from "Ex-Exhibitor" and others their views upon this subject, and suggestions for the best and most effectual manner of testing boilers used for horticultural purposes. It is to be hoped that the Royal Horticultural Society will see their way to include in their exhibition scheme a boiler contest if they consider the matter of sufficient importance.—HORTICULTURIST.

[We understand the Liverpool Horticultural Association will hold its Show as usual at the end of July, so that the fixture of the "Provincial" could not be very well deferred to a later date than that announced.]

YOUR able article on the above which appeared in your last issue would be read with interest and satisfaction by all lovers of horticulture and friends of the "Royal," one sentence especially being worthy of the greatest consideration: "With strong local support and the friendly aid of horticulturists in other parts of the kingdom an exhibition of remarkable beauty may be easily provided." To this, the end of the first paragraph seems to give a satisfactory reply: "The Council was farther assured of the hearty co-operation of the Liverpool officials and horticulturists." There can be no question as to the desirability or, might it not be urged, the necessity of "strong local support" to arrange a successful exhibition. A writer in a contemporary advises the combination of the "Royal" and the Liverpool Horticultural Association as the surest means to this desired end, and without doubt the executive of a Society who in seven years can show a subscription list unequalled by any in Great Britain, whose spring and autumn meetings are second to none, would be of value for advising or carrying out the work in detail, such as advertising, placarding notices, and the many requirements needed for a display of such magnitude. They would also be in a position to gain the public interest for this show, but in the event of their holding the usual Bank Holiday Exhibition their whole energies would naturally be centered for the welfare of the Association.—A LOVER OF HORTICULTURE.

### REVIEW OF BOOK.

*The Miniature Fruit Garden*, edited by T. FRANCIS RIVERS. Ninth edition. London: Longman, Green & Co. 1886.

It is nine years since the eighteenth edition of this useful little work was issued, and another edition being demanded, the nineteenth is now placed before the public. Very few works upon special subjects command such an extensive sale as this has done, and its popularity is a faithful index to its merits, for as a concise practical treatise it is most valuable. The original work was from the pen of the late Mr. Thomas Rivers, but several of the recent editions have been revised by his son, Mr. T. Francis Rivers.

The editor has, however, found little occasion to alter or add to his father's work, and with the exception of two or three small chapters, such as those on "Cordon Trees" and "Seedling Pears," very little is added, for as it is stated in the preface, "Trees do not change their nature, and the rules for their cultivation in one year, if sound, must be the same in all succeeding years." Amateurs and others may rely that the instruction is sound, for it was derived from a life devoted to the study and culture of fruit trees, and abounds in those useful practical hints upon apparently small matters that so often remove difficulties from the paths of the experienced.

Much attention is given to Pears and Apples, which are fully treated of for all their various purposes as pyramids, bushes, cordons, on various stocks, gathering the fruit, &c. Chapters are also devoted to Plums, Cherries, Filberts and Nuts. Then in dealing with general culture there are chapters upon "Seedling Fruits," "Pyramid Orchards," "Double Grafting of Fruit Trees," and many other subjects of a similarly interesting and important character.

In several respects the book has been considerably improved, the page is enlarged, a bolder type is employed, and it is tastefully bound in brown cloth with gilt lettering.

## A COMPARISON OF MANURES FOR THE GARDEN AND ORCHARD.

[A paper by Professor G. C. Caldwell, Ithaca, New York, read before the Massachusetts Horticultural Society.]

(Continued from page 130.)

THAT the presence of decaying vegetable matters or of humus in the soil does increase the proportion of carbonic acid there is fully shown by analysis of the air in the pores of the soil. The air above the soil contains three parts of carbonic acid in 10,000, while that in the soil may contain ordinarily 100 parts in 10,000; and, moreover, such richness in carbonic acid is found only in the air of soils containing humus. A rich dressing of stable manure, or, in other words, a large addition of decaying, humus-forming substance, largely increases the quantity of free carbonic acid in the soil. An Asparagus bed that had not been manured for a year contained in the air in the pores of the soil 122 parts of carbonic acid in 10,000, but when recently manured 233 parts. Another, a surface soil rich in humus, had 540 parts of carbonic acid, a newly manured sandy field 333 parts, and the same soil, in wet weather, 1413 parts of carbonic acid in 10,000 of its air.

This function of the humus of the soil can also come into use with respect to the plant food added in manures. To me, one of the most interesting properties of soil is that remarkable power it has of absorbing certain valuable plant nutrients, holding them in a difficultly soluble condition near the surface, so that, however much rain may leach through the ground, they will be only very slowly carried down deeper, or washed out altogether. Thus the soil behaves with phosphoric acid, with potash, and with the ammonia that is so valuable for its nitrogen. For these three substances any arable soil that is not too sandy is a most trustworthy savings-bank. Therefore, although we should make much account in buying a fertiliser of the proportion of soluble phosphoric acid, or potash, or nitrogen compounds in it, yet in all probability, to say the least, our crops take up but a little of these nutrients before they are changed by this fixing power of the soil into a difficultly soluble condition.

Why, then, it will naturally be asked, should we pay 10 cents a pound or more for soluble phosphoric acid when we can get good insoluble acid for 6 cents or less, if what we put on the soil as soluble so soon becomes insoluble? For this reason, partly, that the even distribution of the food through the soil is a matter of much importance. Anyone can easily understand that if a bottle of the much-advertised, and I suppose very useful tonic, Horsford's acid phosphate, were poured over half a bushel of soil, and washed in with a slight drenching of water, phosphoric acid would be far more thoroughly mixed with that soil than, by any reasonable amount of stirring such as one could afford to give to a cultivated field, he could distribute 2 ozs. of dry superphosphate through the same quantity of soil. So, when 400 lbs. of superphosphate are applied to an acre of soil, in spite of the best of the usual cultivation that could be given to that soil the fertiliser would remain in little scattered particles here and there; but let the rain take it into solution for a short time, and distribute it over the surfaces of many hundred thousand particles of soil, so that the feeding rootlets find it wherever they go, and how much wider and more even the mixing of the fertiliser with the soil will be; and yet, so quickly does the soil seize hold of this travelling plant food, and insolubilise it, if I may borrow a very convenient French word with a very plain meaning, that it cannot stray far off.

Practically, then, every crop has to procure all its phosphoric acid, all its potash, and a part at least of its nitrogen, from difficultly soluble compounds in the soil; and I think it is now easy to understand why, as so often observed, commercial fertilisers do their best work when used with stable manure: the abundance of carbonic acid generated by the fresh application of such manure assists in the re-solution of the insolubilised phosphoric acid and potash of the commercial manure, as well as of the difficultly soluble native food of the soil. Some writers consider this to be such an important function of stable manure that they condemn the practice of allowing it to rot in the yard at all; they would have all the decay go on in the field, just where the products of this decay are needed for their action on the soil. It was somewhat interesting as well as amusing, while I was writing this, to meet with the statement in an English paper that a patent had been taken out in England for charging a soil with carbonic acid through pipes laid near the surface. A few good results of such a system would be worth more in illustration of the principle that I have been explaining than the patent will ever be worth to the inventor. No results are given, but you see that it is exactly what Stoeckhardt did, and I have no doubt that it would increase the yield of crops; but as long as we can still get hold of any humus-forming material at reasonable rates, we have a far cheaper method of attaining the same end.

There are other ways in which humus may, and doubtless does, favour the production of crops; but, to my thinking, all of them taken together do not sum up for so much as does this one way that I have been speaking of.

We can compare stable or other animal manures in another way that may explain the reason why less satisfactory results are sometimes obtained with the latter; I refer to the comparative cost of plant food in the two kinds of manure. You are aware that the Directors of the Experiment Stations of Massachusetts, Connecticut, and New Jersey have, in the past few years, conferred together in the spring to determine what may be considered as a fair valuation per pound of nitrogen, phosphoric acid, and potash, in their various degrees of solubility as found in these manures. The figures thus given represent the retail cost of these substances, in the markets of the State where they are sold as raw materials to be worked up into the various brands of fertilisers offered for sale during the year.

On the basis of this scale of values adopted for 1884 I think it is fair to assume that when a gardener or a farmer buys potash in a commercial fertiliser, with the same degree of solubility and availability for plant food as in ordinary animal manures or other animal waste used for manure, he will have to pay at least five cents a pound for that potash; for phosphoric acid of like solubility and availability as in these domestic manures he would pay about nine cents a pound, and for nitrogen, sixteen if not eighteen cents; I take the lower figure to be sure that I am within bounds.

(To be continued.)

## POTATOES FOR EXHIBITION.

OF late years I have not been able to take an active part in the various Potato competitions, not, however, from any lack of enthusiasm in the matter, but simply because there are too many other and more important duties requiring my attention. Not only must an intending prizewinner be prepared to devote much extra attention to any kind of vegetable with which he hopes to excel, but he must also be prepared for many disappointments, this being in each instance most apparent in the cultivation of prize Potatoes. Under ordinary culture good useful crops of tubers may be obtained, but it is only by extraordinary culture that those extraordinarily fine and handsome samples are secured. Even with the most skilful treatment failures will occur, and this will partially account for the "ups and downs" of various well-known exhibitors. Those, then, who, like myself, are unable to devote plenty of time, space, and manure to the cultivation of show Potatoes may well follow my example and postpone the attempt till such times as the fates are more propitious. It is the mixing up the show Potatoes with those intended solely for the table—or, rather, the unwise preponderance of the former over the latter—that in many cases brings the show sorts into such contempt with employers, who may not object to a few rows of fancy sorts being grown, but rightly complain when they are called upon to eat them. The quarter devoted to show Potatoes should also be known as the trial ground of new sorts, as it is only by a fair trial that anyone can discover a really serviceable variety to replace one of the by no means perfect table sorts that may be found suited to that particular garden soil. Here, for instance, we are obliged to plant Scotch Champion very extensively, but I am in hopes of eventually replacing it with one less ugly, therefore less wasteful, but possessing the more pleasing characteristics of our old favourite. Magnum Bonum we find invaluable, being invariably of the best table quality; yet in a list kindly submitted to me by a friend in Kent, and to which I shall allude at length, it has a black mark against it, this denoting inferior quality, and I mention it here to strengthen my argument that we must rely principally upon ourselves to discern which suit us best, this necessitating a trial.

Although not an actual exhibitor of Potatoes, I contrive to "keep touch" with my old hobby, this being principally accomplished by maintaining a correspondence with old friendly rivals, notably Mr. C. Howard of Bridge, near Canterbury. Mr. Howard is an amateur Potato enthusiast, who devotes his leisure time to the cultivation of the best show sorts—and by best I mean only those that are both handsome in appearance and good in quality. His 1885 record is a good one, as out of thirty-two lots staged at different shows, including the National, he won twenty-seven prizes, sixteen of these being firsts. Every season he tries several new sorts, the weeding out process being also well attended to. Last season four dozen varieties were grown, and twenty of these are now condemned, principally owing to the quality being second rate or even worse. The sorts grown for the last time in 1885 were Cardinal, Clyffe Hall, Early Rose, Edgcott Purple, Edgcott Seedling, Grampian, International Kidney, Magnet, Magnum Bonum, Pride of America, Prime Minister, Prizetaker, Purple King, Radstock Beauty, Red Emperor, Snowdrop (a sort not distinguishable from Snowflake), Sukreta, Victory, and Vermont Champion, also Synonymous and Idaho. Many of the foregoing are described in the catalogues as being of excellent quality, but in all probability the general verdict on them will eventually coincide with Mr. Howard's.

The wholesale condemnation of show varieties by non-exhibi-

tors I do not agree with, but when enthusiasts express the opinion that it is surprising how few really good eating Potatoes there are, we may feel justified in arriving at the conclusion that the only good the tottering International Society is now doing is the keeping of too many sorts before the public, the long lists of glowingly described sorts serving to bewilder and, what is still worse, to very frequently disappoint those who depend upon the catalogue descriptions. What we want, who cannot grow many sorts at a time, is the advice of independent men willing and able to give an honest opinion of the merits of all they have tried. The list of those retained by Mr. Howard should prove instructive, these being Adirondack, Alderman, Fidler's Success (late Beauty of Eydon), Beauty of Hebron, Chancellor, Cosmopolitan, The Dean, London Hero, Duke of Albany, Early Regent, Ellingtonia, Fiftyfold, First and Best, Ashtop Fluke, Mr. Breeze, Pride of Ontario, Fidler's Prolific, Queen of the Valley, Reading Hero, Reading Russet, Snowflake, Vanguard, Vicar of Laleham, Woodstock Kidney, White Elephant, and Scotch Blue, and to which are added this season Sutton's Seedling, Sutton's Abundance, The Colonel, Purple Perfection, Earl and General Gordon, these being of promising appearance.

What Mr. Howard considers a good twelve for both "table and show" are Chancellor, Snowflake or Woodstock Kidney, Fidler's Prolific, Schoolmaster, London Hero, Reading Hero, Beauty of Hebron, Edgott Purple, Mr. Breeze, Vicar of Laleham, Reading Russet, and The Dean. Where table quality is the greatest consideration he recommends the Ashleafs, Beauty of Hebron, Snowflake, Harvester, Alderman, Early Regent, Woodstock Kidney, Reading Russet, Schoolmaster, any of the Lapstones, and Reading Hero, and these used somewhat in the order given will last "in good eating all the year round." Of the foregoing the heaviest croppers are Queen of the Valley, Adirondack, Vicar of Laleham, The Dean, Fidler's Prolific, Success, White Elephant, Duke of Albany, Cosmopolitan, Fiftyfold, and Chancellor. The last-named Mr. Howard considers the finest cropping white kidney he has yet grown, and is of opinion that it will never be surpassed either for heavy cropping or exhibition.—W. IGGULDEN.

#### SHRUBBY CALCEOLARIAS.

CALCEOLARIAS are favourite bedding plants here, and in order to succeed with them I have been obliged to considerably modify the details of their treatment from that usually considered correct. The usual method of culture in many instances fails in securing beds of healthy plants, free flowering, and bright in colour. Therefore a short note on this subject may be of benefit to gardeners and others who have hitherto had some trouble with Calceolarias.

I do not think it matters much which variety is grown, that being merely a question of taste. The two I like best are Kayi, a strong-growing floriferous yellow, which from July till November affords a continued succession of bright flowers; and General Havelock, a brownish red, sort which under special treatment is as long-continued a flowerer as Kayi. This is more of the habit of the herbaceous varieties, and can hardly be called "shrubby." The flower heads are produced in moderate abundance from the dwarf growths which form the plant, and by removing the older growths a continued succession of flowers is obtained. If, however, the old flower heads are left too long the plant leaves off flowering. I have tried a large number of other sorts, but have found none to do so well as these. *C. amplexicaulis* is a beautiful variety, and is worthy of cultivation both for its beauty as a plant and for yielding a supply of flowers, but as a bedding sort it does not do so well as Kayi.

There are two main points in the treatment of Calceolarias as bedding plants which are of much importance. The first is to take the cuttings so late as to insure the plants making no top growth before spring, and the second to have the plants put into the flower beds as soon as can be safely done after they are well rooted. In order to secure the first of these I find the third week in October quite as early as the cuttings should be inserted. They may be left till the beginning of November, but, all things considered, perhaps the former is the time to be preferred. At the present time the cuttings are beginning to make roots, the tops, as a matter of course, being in exactly the same state as when they were dibbled into the frames. The appearance is not so good as that of plants which were rooted before winter, but they are just in the condition to form compact little plants, each having a ball of roots, which can be transplanted intact in the beginning of April into the flower beds.

A layer of old Mushroom-bed manure over the bottom of the bed is a great help to securing plenty of short healthy roots at transplanting time. The beginning of April is about the time to do this. When planting a little manure is worked in amongst the roots, and after the planting is finished a layer of the same spread over the beds is of very great advantage. As each plant is put out a few twigs of dead spruce branchlets are stuck round it. This serves as a protection from cold, and later on helps to support the plant as it spreads out in growing. The plants are kept free from flowers until June, when they are left to come on, so as to be well flowering by the beginning of July. If the weather is very dry about the end of May a soaking of water is given, and any time afterwards, if dry weather sets in for any length of time, the beds are soaked

with water. Under the conditions above noted we lose scarcely any plants, and I have never seen plants do so well even when double and perhaps treble the amount of labour was expended on them.

It only remains to add that the last cuttings are those not above 2 inches in length, and if they can be had as side shoots, which can be broken off from the main growths, these are all the better. The cuttings are dibbled into cold frames, protected with straw and mats from frosts, and when once the roots are protruded and growth begins the sashes are kept as much as possible off the plants.—R. P. BROTHERSTON.

#### SOME SINGLE ROSES AS DECORATIVE PLANTS.

[An article by Mr. T. W. Girllstone in the "Rosarian's Year Book"]

(Continued from page 136.)

PERHAPS the most winning of the smaller-growing single Roses is *R. berberidifolia* Hardii (I.), formerly said to have been a hybrid between *R. berberidifolia* (= *simplificifolia*) and *involucrata*, but probably a seedling from *R. clinophylla* fertilised by *R. berberidifolia*. Anyway, the plant was raised by M. Hardy, at Paris, in 1844 [Date not certain.—T. W. G.] and though not simple-leaved, it follows *berberidifolia* in its yellow flowers, about the size of half-a-crown, with a purple blotch at the base of each petal. Its habit is slender, but it grows and flowers freely, and makes a most graceful and interesting plant.

Another Rose that is a first-class plant, in spite of its being afflicted with a list of names like a biographical dictionary, is *R. Sinica* (III.) (= *lævigata*, *ternata*, *triphylla*, *nivea*, *camellia*, *cherokensis*!). It would almost seem as if there had been (of course there are not now) people who on finding some well-known plant to be possessed of great merit, have got up stock, and sent it out afresh with a new name. At any rate, most of the best varieties of Apples, Pears, *Chrysanthemums*, *Roses*, &c., appear to have such a string of names, that it is like being at a Royal christening to hear them talked about. Could some such practice as this have originated the use of the word "plant," to signify a "take-in?" this of course, *sub rosa*. But to return; of all *Roses*, *Sinica* is the most easily recognisable, with its ternate, dark, glossy foliage, in texture more like that of a *Camellia* than a *Rose*, and it is admirably adapted for covering either a wall or pillar, since, in addition to being practically an evergreen, it grows with great vigour, and when established makes a lavish display of its beautiful large single white flowers. It is often called the Georgian *Rose*, from the land of its adoption, in North America, but it is believed to have been originally introduced from China.

The other Chinese *Rose*, *R. bracteata* (IV.) (Macartney) and its pretty variety, *Maria Leonida*, are two very charming *Roses*, but well-known, and perhaps hardly of sufficiently robust constitution to become general favourites. From North America, however, have come several species of considerable interest, especially two which have a more or less strong family likeness in their principal features. These are *R. nitida* and *R. lucida* (= *baltica*, *rapa*) (V.), both characterised by shining leaves composed of many (five to eleven) small oblong leaflets, stems more or less red and smooth, and rosy flowers succeeded by scarlet setaceous Turnip-shaped hips of great brilliancy. The former is the more slender plant in all its parts, and the shoots are covered with numerous fine prickles of various sizes, which, however, are not always persistent; but it is a fairly easy plant to identify, and is very well figured by Redouté. *R. lucida*, on the other hand, is a very variable species, though always attractive, with its glossy foliage to set off its rosy flowers or brilliant fruit, neither of which vary appreciably. One variety is a vigorous grower and makes a large bush, or if trained on a wall attains the height of 10 or 12 feet, and has obtuse pale-green leaflets with an uneven surface, and numerous deciduous prickles on the young growths. But the most beautiful variety does not usually exceed 2 feet in height, although very vigorous; its dark red stems armed with pairs of straight prickles support pretty rosy flowers, which are succeeded by round hips even more ornamental, gleaming among the deep green shining foliage, which itself assumes a rich purple colour before reluctantly admitting that it is not quite evergreen. In the same group (V.) *R. Woodsii* is not so interesting, but the foliage assumes pretty tints in autumn; the slender-growing *R. clinophylla* (= *laxa*) is best known through its beautiful double-flowered variety; and *R. rugosa* (= *ferox*, *Regeliana*) is generally cultivated. The white-flowered variety of the last-named is deservedly popular, but the variety *coruscans* should be grown rather than the red-flowered type. For it must be admitted that the colour of *rugosa* is of a somewhat dingy red, while *coruscans*, of similar external appearance, has flowers of the softest clear pink, with petals of wonderfully silky texture. A rich purple semi-double variety called *Comte d'Espremenil*, sent out by Nabonnand, is of interest as being perpetual, flowering freely a second time in the autumn. *R. kamtschatica*, with a habit of growth somewhat similar to *rugosa*, is inferior in every way, having much smaller red flowers.

(To be continued.)

#### ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday evening, the 17th instant, at the Institution of Civil Engineers, Mr. W. Ellis, F.R.A.S., President, in the chair.

Mr. G. Buchanan, M.Inst.C.E., Captain G. H. Leggett, Dr. H. C. Taylor, J.P., and Mr. J. Tolson, were ballotted for and duly elected Fellows of the Society.

The following papers were read:—

1. "General Remarks on the Naming of Clouds," by Capt. H. Toyn-

bee, F.R.Met.Soc. The author considers it important to keep to Luke Howard's nomenclature, leaving it to the observers to express by an additional word any peculiarity they notice in a particular cloud.

2. "On the Thickness of Shower Clouds," by Mr. A. W. Clayden, M.A., F.G.S. From some measurements made by the author during the summer of 1885, he has come to the conclusion that clouds of less than 2000 feet in thickness are not often accompanied by rain, and if they are it is only very gentle, consisting of minute drops. With a thickness of between 2000 and 4000 feet the size of the drops is moderate. As the thickness gets greater the size of the drops increases, and at the same time their temperature becomes lower, until, when the thickness is upwards of 6000 feet, hail is produced.

3. "On the Formation of Rain, Hail, and Snow," by Mr. A. W. Clayden, M.A., F.G.S. The author points out that all observations tend to show that, except under quite abnormal conditions, the temperature of the atmosphere falls as the height above sea level increases, and there seems no reason whatever for assuming that the law does not apply to that portion of the atmosphere which forms a cloud. Hence, if a drop were to be formed at or near the upper surface of a cloud it would fall down into a region saturated with vapour at a temperature above its own. The result will be further condensation, producing a larger drop; and this process will continue until it leaves the cloud. If its temperature is below the dew point of the air it falls through, condensation will continue until it reaches the ground. However, it is obvious that this subsequent gain cannot bear any very large proportion to the growth while falling through the saturated cloud, from which the conclusion follows that the size of the drop must increase with the thickness of the cloud. The author suggests that condensation begins on the upper surface of the cloud by the cooling of some of the liquid cloud particles. If this particle is cold enough it will solidify, and snow will be formed. Should it not be quite cold enough to solidify at once, owing to its minuteness, but remain still below the freezing point, hail is formed. Finally, if the temperature is not low enough for either snow or hail rain is produced.

4. "On Three Years' Work by the 'Chrono-Barometer' and 'Chrono-Thermometer,' 1882-1884," by Mr. W. F. Stanley, F.R.Met.Soc. The Chrono-Barometer is a clock that counts the oscillations of a pendulum formed by a suspended barometer. The upper chamber of the pendulum is a cylinder of an inch or more in diameter. By change of atmospheric pressure the mercury in the pendulum is displaced from the bottom to the top, and *vice versa*. The rate of the clock is accelerated or retarded in proportion to the displacement of the mercury. The Chrono-Thermometer is a similar clock to the above, and the pendulum is also a barometer; but instead of the lower chamber being exposed to pressure the whole tube is enclosed in a second hermetically sealed tube containing air. Atmospheric pressure being thus removed, the expansion of the included air by heat alone forces the mercury up into the vacuum chamber and alters the period of oscillation of the pendulum.

## CULTIVATION OF THE OLIVE AND WATTLE IN AUSTRALIA.

Two reports furnished recently to the Legislative Council of South Australia by Mr. J. E. Brown, the Conservator of Forests in that Colony, contain some useful suggestions relative to these trees. Mr. Brown shows that such culture should afford good returns for the labour bestowed on the tree. According to his experience, the climate and soil of many parts of Australia are highly suited to its rapid and successful growth, and from the excellent oil which has already been produced in South Australia from the fruit there is every reason to conclude that a highly remunerative and permanent industry could be established in our midst by the extensive cultivation of the tree. It is no exaggeration to state that both the climate and soil of Australia are in many respects more generally suited to the growth and fecundity of the olive than are these physical features of its indigenous habitat. Where land is already fenced and cleared the planting of Olives would cost, ordinary farm labour being employed, about 40s. per acre. The trees, planted 15 feet apart, would give 70 trees per acre. They should come into full bearing between the tenth and twelfth year's growth, from which time the nett yearly proceeds would be about £3 per acre. It is said that the Olive tree reaches maturity between the fiftieth and sixtieth year. It, however, continues to bear prolifically after that period, and has been known to live until the age of 300 years and more. There is a great variety of Olives. Some grow successfully only in moist and temperate climates, while others again do best with less moisture and a comparatively high solar heat. Again, some varieties are disposed to favour soils of a fairly rich character, but which are free in consistency; while other varieties prefer sites where the soil is of a warm calciferous character. From these facts, therefore, it will be seen that in the predilections of the various varieties of the Olive tree, both as regards soil and climate, there could be selected kinds to suit the various local physical peculiarities of our vast agricultural areas. The great drawback to the industry is the fact that a dozen years must pass before a monetary return can be had for the labour bestowed. Australian farmers are advocates for quicker returns, but, nevertheless, they might in that leisure time which occurs on most farms devote a few hours to the planting of Olive plants, the cost of which Mr. Brown estimates to be about 2d. each.

Many farmers of Australia are fully cognisant of the profits derivable from Wattle trees, although few have done much in the shape of planting. The Forest Department of this colony is at present making an experiment

with Wattles on the vacant ground along railway lines; and Mr. Moses, a tanner of Armidale, has a Wattle farm. Mr. Brown shows on paper that Wattle cultivation, although years have to elapse before a return can be expected, is a branch of agriculture which will pay handsomely. He says:—"At the distances apart which I recommend the trees to be grown—namely, 4 feet to 6 feet—there will be an average of 1200 trees to the acre. In order, however, to make due allowance for barks, I shall base my calculations upon there being 1000 only to each acre. At the present time bark is selling at £7 10s. and £8 per ton, and there is every chance of a still higher price being obtained for it during the next few years. Still, to be on the safe side, I will put its value down at £5 per ton only. I give 5 tons as the probable yield per acre. That this is a low estimate will be admitted, when it is considered that this only allows for 10 lbs. of bark to be taken from each tree. I shall now give a statement of the probable revenue and expenditure during a period of seven years, in connection with a Wattle plantation, formed upon 100 acres of land specially purchased for the purpose, and upon which Wattles had not previously grown." The expenditure, allowing £3 per acre as the price of the land, would be £1792; the returns would be the value of 500 tons of bark, £2500; value of property, say £400: total, £2900. The profit, therefore, would be £1108.

## HARDY FRUIT GARDEN.

WITH the pruning and training of Peaches, Nectarines, Apricots, and Figs our winter work in the fruit garden is finished, with exception of Cob-nuts and Filberts, which are not pruned till after the catkins are fully developed, and enough of the yellow pollen is shaken from them to impregnate the little pink brush-like female blossom. In pruning and tying in the lateral growth of Figs, thin out crowded growth, but shorten no shoot which you reserve for fruit-bearing, because the fruit comes at the two or three top joints of each shoot.

In a well-managed fruit garden we now find the pruning and training of wall and espalier trees finished. Old fastenings have been examined and renewed where necessary; particular attention has been given to training the pliant growth of young trees to a correct form—and, remember, to impart any form to a fruit is only a matter of time and painstaking; all newly planted trees are fastened so securely that no wind can loosen stem and roots in the soil—we are most particular to have this well done, knowing, as we do, that unless the soil is packed closely about the roots a tree cannot thrive; mulching has been placed over the soil about every newly planted tree. A label of lead or other metal with the name stamped so deeply upon it that it is practically indelible, has also been fastened to the stem by a thick leaden wire coiled round it in such a manner that it will yield to the pressure of the expanding growth and not clasp the bark so closely as to become embedded in it; the name of each tree is also written on a plan of the garden in the exact position it occupies in the garden, as a precaution against the loss of labels, and for reference in the garden office. Earnestly do we impress upon all fruit growers the importance of this simple plan, for in nothing is there more carelessness than in keeping names to fruit trees. Quite recently a gentleman with an extensive collection of fruit was deploring the loss of names, and he might well do so, for he had originally spent £5 upon labels for them; many of the labels are now lost, and there is no plan for reference. The fruit trees are just coming into full bearing; how is the owner of them to derive pleasure from the comparison of sorts, or his gardener to acquire such knowledge of them as he ought to have?

All hush fruits should have had a top-dressing of half-decayed manure applied in autumn. If this was not done, let no time be lost in now doing it, and see that the soil among the hushes is not disturbed by digging, which only destroys surface roots and does more harm than good.

## FRUIT FORCING.

VINES.—*Grapes in Flower*.—The temperature must not be less than 60° to 65° at night, with a rise of 10° to 15° by day. Discontinue syringing, keep the glass clean, and prevent condensation of moisture by a little ventilation constantly, but without causing a draught. Shy-setting varieties will require careful fertilisation, even Black Hamburgh well repay the trouble by producing heavier bunches of evenly formed berries. Muscats in bloom should have a night temperature of 65° to 70°, and 10° to 15° rise by day; and if they are numerous a better set may be secured by the removal of the surplus bunches before they flower.

Thinning.—Keep thinning well in hand, as every swell of the berries means so much taken from the size of those that will ultimately be retained for the crop. Rules for thinning cannot well be given; it requires judgment, the capabilities of the Vines being taken into consideration. The thinning, however, should be such that a sufficient number of berries be retained to prevent the bunch falling out of shape when cut and laid upon the dish, there being just space for each berry to swell to its full extent without wedging or losing its natural form.

Stopping, Tying, and Regulating the Shoots.—Attend to disbudding as soon as the best breaks can be discerned, but it is a work that should

be done gradually. Stopping may take place one, two, three, or four joints beyond the show of fruit, as the space admits; but the greater the growth beyond the fruit the more certain is it of being well supported. We prefer stopping at the third or fourth joint beyond the bunch, and then allow the laterals to extend until the available space is covered with an even spread of foliage, and then keep closely stopped. If the space is limited stop at the second joint, or even one beyond the bunch, as it is desirable to have an extension of lateral growth and as great a spread of foliage as can have exposure to light and air. Tie the growths down before they touch the glass, bringing them down carefully, as the growths of vigorous Vines are liable to snap. Loosen all ties, so as to allow the swelling of the shoots.

**Feeding.**—Fruiting Vines in pots will need fresh surface dressings of rich material, well-decayed manure, with a sprinkling of bonemeal and copious supplies of liquid manure in a tepid state, keeping the plunging material about the pots well moistened with the same to insure the spread of the roots into it, and augment the support of the Vines. Vines swelling their crops will need liberal supplies of liquid in a weak and tepid state, and the surface of the borders mulched with 2 or 3 inches thickness of manure kept moist to encourage surface-rooting. Maintain a genial condition of the atmosphere by damping available surfaces two or three times a day, especially at closing time, which should be sufficiently early to run up the temperature 5° to 10° over the ordinary day temperature from sun heat. Sprinkling the floors with liquid manure in the evening will invigorate the Vines and prove injurious to insects, particularly red spider.

**PINES.**—As the summer, or what is known as the London season, is the most important to growers under the changed circumstances that obtain in Pine Apple culture, winter fruit commercially being out of the question in competition with foreign fruit, the cultivation of summer varieties has been greatly extended, among which the Queen stands unrivalled, both on account of its excellent quality and its adaptability for the purpose, good fruits being obtained in eighteen months from the starting. It is well to have two groups of plants, one being a selection of the most vigorous of the autumn-potted suckers which have been kept moving through the winter, these plants being put at once in 10 or 11-inch pots, and plunged in a bottom heat of 90° at the base of the pots. The others are those started about this time as suckers, which as soon as they are sufficiently rooted are shifted into 10 or 11-inch pots and plunged in a similar bottom heat. Keep the night temperature at 60° to 65°, and 70° in the daytime by artificial means, with an advance of 10° from sun heat. It is essential that the plants have plenty of space, and be kept well up to the light, as a good sturdy growth is essential to success. Where rootless suckers are placed, keep the atmosphere moist and close, and withhold water until the roots are showing at the sides of the pot.

**STRAWBERRIES IN POTS.**—Unsuitable weather for forcing necessitates continued vigilance and perseverance in forwarding early crops. A good set having been secured on the earliest plants, and being thinned to the number likely to swell satisfactorily, they should be removed if possible to a house with a maximum temperature by artificial means of 65° to 70°, a Cucumber or Melon house being suitable until the fruits begin to change colour, as they swell best in a high moist atmosphere, but when ripening a drier atmosphere is necessary. The change of temperature must not be sudden or the fruit will not swell freely; indeed, the temperature should remain the same so as to secure a clear skin and bright colour—the great merit of a forced Strawberry. Feed liberally during the swelling period up to changing colour, giving it warm and weak, and if the roots are in good condition they will take large quantities if evenly swelled fruit is desired.

#### PLANT HOUSES.

**Vandas.**—These, as well as *Aerides* and *Saccolabiums*, should be top-dressed or repotted, as the case may be. Those that were repotted last year will only need top-dressing. Whether the plants are grown in pots, pans, or baskets, the whole of the old material should be removed and fresh chopped sphagnum moss supplied. When all the material has been removed to the crocks or charcoal used for drainage, or as a medium for the lower roots, if any small decomposed particles remain they should be washed out by pouring tepid water into the pots, or by dipping them into a tub of water. These must be allowed to dry again before the new top-dressing is applied. For this purpose sphagnum moss only should be employed. No attempt should be made to cram the roots into the pots, for they will remain much healthier outside. The moss should be well elevated above the rim of the pots or sides of the baskets, and the greenest and best heads used on the surface, encouraging them to grow afterwards by frequently dewing the surface with the syringe. When repotting is necessary the material should be carefully picked out of the roots, crocks, and drainage, as well as the moss, and the plant lifted out of the pot if possible; if not, the pot must be broken and any portions left to which the roots are clinging. Place a fair quantity of crocks at the base of the pot, in fact as many as can be conveniently put in before the plant is in position. When this is done, if a stake is needed, give it at once, as it cannot well be secured afterwards when the pot is filled with crocks. After the plant is in position, the crocks, charcoal, or both should be laid carefully amongst the roots, filling the pot to within 2 inches of the rim. On the surface use a few smaller crocks to prevent the moss being washed down amongst the lower drainage. Fill the remainder of the pot with moss, the same as advised for top-dressing. When the plants are turned out cut away all dead and decaying roots with a sharp knife. When plants are growing in baskets it is often impossible to take them out without destroying a large quantity of roots. The safest method is to remove as much of the basket as possible, and then place the remainder, with the

roots attached, into the larger ones. The space between the two baskets—that is, the new and the old one, should be filled with lumps of charcoal and then surfaced with moss to sustain plenty of moisture about the plants. From this time never allow the moss about the plants to become dry, and keep the atmosphere moister than has been the case up to the present. Do not syringe these plants for a few weeks, except giving a slight dewing during the mornings of very fine days. The temperature for this structure must not fall during the night below 65°, except during very cold nights. No ventilation will be needed at the present time.

**Phalaenopsis.**—If grown in the same house as the above, the conditions as regards heat and moisture will suit them exactly. It is necessary to watch these plants carefully, so that yellow thrips do not become established on the under side of their beautiful leaves. If observed, sponge at once with a weak solution of tobacco. These plants are grown here in baskets in lumps of charcoal and sphagnum moss; the former nearly fills the baskets, and the latter is worked in amongst them towards the sides with a good layer on the surface. The moss becomes too decayed for their well-being in a single season, and is in consequence removed annually. All small particles are washed out the same as advised for *Vandas*, and then fresh is given. When new or larger baskets are required, no attempt is made to disturb the roots by the removal of any portion of the basket until thoroughly decomposed, so that it can be removed without the slightest injury to the roots. Place the old basket inside the new one, and fill the space between with charcoal, and then moss it over as detailed for top-dressing. After potting or top-dressing, the moss should be encouraged to grow freely by syringing frequently, the use of the syringe being increased as the days lengthen and the atmosphere outside becomes warmer. Any plants in full bloom may be left for a time, so that the syringe need not be used for fear of spotting their flowers. The flowers of these plants, as well as those of any other Orchid, last much longer in a cooler and drier atmosphere, but we never remove *Phalaenopsis*, for in the past we have had them seriously checked by so doing.

**Cypripediums.**—The majority of these that are growing in warm structures may be repotted and top-dressed without farther delay. Any plants in flower or coming into flower that it may be necessary to remove to a cooler structure may be left until the flowers have faded. For these plants we prefer peat fibre and sphagnum moss in equal proportions, with lumps of charcoal freely intermixed. We usually employ the peat fibre and charcoal towards the base; in fact, fill to the rim of the pot, and then the remainder with the sphagnum intermixed. The fibre does not decompose so quickly as the moss, and by this means the whole of the upper portion is removed annually, which insures a sweet compost about the roots of the plants without the removal of the whole every year. The majority of *Cypripedes* will stand without apparent injury decayed compost about their roots for a longer period than most Orchids; but this is not desirable, for they prefer a sweet medium. When plants are left too long with their roots amongst sour soil they are liable to become spotted in their foliage and seriously disfigured. When these plants are repotted it is often necessary to break the pots or pans in which they are growing, for the roots cling tenaciously to the sides and cannot be turned out without injury. When removed from their pots take every particle of soil from amongst their roots, and if in a very bad state the roots should be washed before they are placed in clean pots with fresh material. Place a good layer of moss on the surface, and encourage it to grow after the completion of potting and top-dressing. The plants may be lightly syringed when there is a prospect of a fine bright day. Care must be taken that tepid water be used for this purpose, and also for watering these as well as all other plants in this department. Much injury is often done by inattention to this, as plants of *C. insigne* cease flowering in the conservatory. They should be started into growth where a temperature of 50° can be maintained at night. *C. villosum* now in flower will take its place in the conservatory and be benefited for a few weeks by being in a lower temperature. *C. venustum* is employed for the same purpose.

## THE BEE-KEEPER.

### ABOUT BEES.

(Continued from page 140.)

THERE has been a great number of runaway swarms. A neighbour keeping bees in skeps lost three out of four hives, and two cottagers have secured swarms that came from a hollow tree colony. I was asked several times if I had lost any swarms, as several had been found, but I always was asked after they had been secured. Unfortunately none of the runaways came my way, as I should have been delighted to make their acquaintance, particularly the swarm from the wild bees in the tree, and I failed to purchase one of the wildling swarms.

What I failed to purchase were given me, and had to be sent some fifty miles by rail. They came to hand in September in a skep, and apparently all right, the hive being, of course, inverted, or bottom upwards. I intended keeping them in the skep, so had a stand made, and as there was only the turning over to do after removing the covering, I merely threw the dress over my

head, and turned the hive right side upwards. Imagine all the combs had broken from their attachments and fell on the board in a heap. There were no cross pieces in the hive, and it was only what might have been expected. Without loss of time I got a hive, one that the bees had died out of in spring, full of store, and set to work to get the bees out of the skep into it. I had to take every piece of comb and brush the bees off—no easy matter, as the other bees had sniffed the nectar, and would not be driven from the spoil. I brushed all in, friend and foe alike, keeping a sharp look out for the queen, and found her at last in the hive smothered with honey, but able to crawl, and I put her in and placed the cover and top on. The dress being only thrown over the head the bees got inside, and in the endeavour to get out became irritated and stung me in the lip. I had four distinct stings that I could make out afterwards, but there was no time then for such trifles; off went the dress, and into a pail the comb and bees, for it was black with rogues or the rightful owners. I left them in that way, for it occurred to me that to take them away might cause the strangers, if there were any on the comb, not to get back to the hive, and with smoker I returned and soon cleared out the bees and covered the comb. As I expected, there were many of the bees with the comb, the rogues sped home or fell on the debris, the rightful bees settled on the shrubs near, and resting awhile took wing. After awhile I saw them gathering in as after hiving at swarming, and then I noticed a fierce struggle taking place, bees trying to get into the hive, bees rushing out, evidently those put in with the rightful ones off the comb, and fighting going on all along the flight board. I narrowed the entrance, and then none entered from the outside but those having business, and to ease matters inside lifted the cover and quilt and let out a cloud of bees; never were prisoners more happy at release. I thought of nothing but the bees outside now, as they had ceased drawing, but as night came on they made for the hive, and most of them landed safely, though I have no doubt many were lost. The work of ejecting the dead I found going on after dark, and in the morning the number in front of the hive was considerable. The bees held their own, and kept it. The swarm was a second one.

This brought the total up to twenty, so that by one means or other I have just doubled the stocks. I fed all in late summer and autumn until they would not take any more down, and then covered them for the winter. The wet I found had got into three hives, the chaff enclosed in bags filling the cover was saturated and the quilts soaked. I found the bees all right, so put fresh quilts and dry chaff, and stopped the crack in the cover with white and red lead, hoping for the best. Though there are second swarms there is plenty of uncapped cells. The bees in these hives only occupy about half the bars, but I did not move the dummy so as to contract the hive as I was told I ought, and as everybody does, only I did so last winter with some, and others not, and I found the last did far the best, filling the whole of the bars or hive sooner, and swarming sooner by a fortnight. If we have sun and warmth I shall feed the bees; if the cells are filled with syrup they will sooner fill the supers with honey, and I shall use peameal outside under cover if necessary, and await the issue.

I will now allude to how five stocks only were profitable as regards swarms, though six swarmed. The stock was a second swarm of the year before, and one that had the hive contracted in winter. It looked liked swarming for quite a fortnight before it issued, and I thought it would never come, but one day the bees rose and kept on the wing a considerable time, and instead of clustering settled on the shrubs in the locality of the hives, being spread over a large area. They were evidently tired by their prolonged flight. They did not draw home quickly, and I concluded the queen had gone away with at least a portion of her subjects, which, however, proved mere conjecture, as upon examining the stock hive I found the queen on the ground directly in front of the hive, and struggling to escape from the few bees that surrounded her. I had a hive in place of the stock in no time, and put her majesty inside from the top, and the poor creature made frantic efforts at escape from the hive, and strove to take wing when on the top of the bars. She appeared incapable of flight, and did nothing but run about the bars on the foundation comb. The bees came in now rapidly, and I put on the quilt and cover, and made them enter by the entrance, watching to see that the queen did not escape. After a time I lifted the quilt and found the bees clustered at the top of the bars, and so concluded that the queen had been accepted, but to my consternation shortly after found there was none of the "knitting"—I know no better term for it—going on, as is the case when bees have been hived after swarming, and at all times when there is a queen in the hive. I got in all the bees I could,

indeed a strong swarm, and then moved the hive to another place, and replaced the stock hive in its old position. The bees all left the hive and returned to the stock, and what became of the queen I could not discover. She was not in the hive dead nor near it.

A general idea prevails that the queen leads in swarming. I think this entirely erroneous, as I have seen bees in search of a domicile long before the swarm has issued. In one instance I noticed a complete line over 200 yards from where bees were located in the roof of a house to another building, which they searched all around the eaves, and continued to do for several days before a swarm issued, which took to another building much further off, but in the same direction they had been scrutinising previously, and they went to it straight as an arrow. I have noticed that in swarming there are some bees in advance of the others, and the queen, especially when the bees rise high, comes out late, the bees being very much spread as if in search of, or to prevent her escaping. Wild bees, no doubt, have their destination marked out before they set out, or they would not go direct to hollow trees or the roof of buildings, though the queen may not be able to accomplish the journey in the first instance without settling or resting or coming in contact with trees have the journey arrested. Even hive bees exhibit this instinctiveness, especially those of skeps; but those of bar frames, being more domesticated, show it by not going far before settling, even joining another before going in search of a domicile to themselves, necessity in this, or in other things, being the mother of invention. In doing the queen does not go up until a number of bees have left, so that we may conclude she does not take the lead in swarming, but is entirely a ruler only by the expressed desire of the subjects.

Though there were Ligurians and Carniolians within half a mile, it was not until this year that our stock showed any trace of cross-fertilisation. One of the second swarms has many half-bred Ligurians mingled with the black, and I presume the mother was crossed by a Ligurian drone, and that the progeny will be half breds, the stock entirely of this character as the blacks die off.—G. ABBEY.

#### FEEDING BEES—MANAGEMENT OF STOCKS.

WOULD "Felix" say if I have done right in giving (Feb. 7th) three of my lightest stocks candy? because those three have come out in greater numbers since than any others, and have sought water in some spouts attached to my greenhouse 10 or 20 yards away, and very many perished therein. Another point I desire enlightenment on is stocks. After having thrown the first swarm are they queenless for eight or nine days? If so, I should like to know if I can join a queen to them just after swarming? I have only one stock in a frame hive, and I purpose feeding it up from 1st of April to 1st of May, then take an artificial swarm; eight or nine days after that to lift every frame containing a queen cell out, putting them into a large hive I have made to hold twenty-four frames with an entrance opposite every four frames, as I place the frames in putting a frame of foundation on each side of them, then a division board, and so on till the hive is full. Is it a wise plan? If not I should be glad to have its defects pointed out. I have eight stocks altogether. They seem all right as yet. I hope to get about eight swarms in spring from them, but not having much room for them I intend advertising them for sale soon. I should be glad to learn if, when packing them for a journey, they will be able to eat through one or two thicknesses of canvas, similar in strength to manure bags, if I use that material to cover the mouths of the skeps.—J. T., *Yorks.*

[If your stocks were so light as to cause anxiety lest there should not be a sufficiency of food to sustain the bees until a more suitable time for feeding had arrived, you followed the customary course in giving candy instead of syrup, the preference being given to the former because the latter excites the bees to greater activity than is good for them at this early season. Bees, however, are naturally now all anxiety to commence work, breeding already going on extensively in many stocks; hence the slightest interference with the hive, much more administering food of any description, will cause excitement, which will be increased if the bees are not numerous enough to throw off moisture sufficient to soften the candy, and they have therefore to go to the fields to get water to soften the cake provided for them before they can make use of it, if the water is not supplied by the bee-master within the hive. In these early journeys many inevitably perish chilled by the cutting winds of spring, and if in addition they seek water in vats or even in spouts, where water is allowed to lie in sufficient depth, many will perish. Probably in your case the cold had chilled them and rendered them unable to return home. If they do get "drowned," the only remedy is to supply water either in the hive or near the apiary, and if the latter place in it straws or stones, upon which the bees may rest in safety and so escape from danger.]

The stock from which a first swarm has issued is without a queen, generally speaking, for about ten days, while that from which a swarm has been driven is queenless for fourteen, unless it should so happen that queen cells had already been formed and tenanted before the swarm was

made. The advantage of giving a queen, or a ripe queen cell even, will be manifest, for if a stock be swarmed on the 10th of May artificially there will in ordinary cases be no queen hatched until the 24th, and on an average, say four days will elapse before fertilisation is effected, and ten days after fertilisation, before egg-laying commences, thus it will be the 19th of June before an egg is deposited. If, however, a queen is given, even if unfertilised, or even a ripe queen cell, on the 10th, on the 24th egg-laying will commence, and the stock will rapidly gain in strength. By all means introduce queens or queen cells as speedily as possible, observing usual precautions immediately after the issue of a swarm.

In another article I will endeavour to show the best means of bringing a stock up to swarming point at the earliest possible moment, so this point as regards stimulating may be passed over without further comment.

The method of procedure proposed with the frame hive is objectionable in every way. A strong stock is spoilt unnecessarily; the nuclei are placed under the same roof, with entrances in close proximity, thus insuring the death of some of the young queens, who when returning from their marriage flights may easily mistake their own abode. The foundation cannot be drawn out, for there will not be bees sufficient, and amongst other objections the heat of the nuclei will be perilously reduced without necessity, so that the queens even if they emerged from the cells might very possibly be of inferior quality, and most certainly would be inferior to those raised in the usual manner under more favorable conditions. Far better to utilise the hive in the usual way, either as one large hive, contracted if necessary, or as two moderate sized ones, having the entrances as far apart from one another as possible. What I would suggest as an alternative to this method is to take an artificial swarm from the stock in the bar-frame hive in the usual manner, allowing the bees to raise their own queens in their own fashion. When the time has arrived when the queen cells are ripe the rest of the stocks may be swarmed, and one queen cell be given to each, and this may be done with little difficulty if only ordinary care is exercised; carefully lifting out one of the frames on which queen cells are seen, cut off the cell with a piece of comb attached, taking every precaution not to crush the infant queen. This cell may now be placed in the stock from which a swarm has been taken, putting the queen cells pointing downwards between two combs, and fastening it in position, the bees when once they have missed their sovereign gladly accepting a successor thus easily given. By this means time is saved, and the stock from which the cells are taken does not suffer in the least if one cell be left.

Unless swarms are desired they may be with almost certainty presented, but if increase is desired the swarm may be safely packed in a skep, and the bees will be quite secure if a piece of cheesecloth be stitched over the mouth of the skep, and a plain label be annexed "This side up." The alternative covering you mention would no doubt answer the purpose, but cheesecloth is preferable and not expensive. For very long distances wire fly-proof netting may be necessary.

The questions were of such general interest to bee-keepers that I have answered at greater length perhaps than the Editor wished, but if so, a desire to make my meaning plain must be my apology for trespassing upon his valuable space.—FELIX.]

### TOMTITS v. BEES.

ON carefully looking over Mr. Hiam's remarks on bees and their enemies, I was surprised to find that our able friend agreed that the little birds—namely, the tomtits, were harmless. I differ from Mr. Hiam on this point. I find them very destructive among our hives during the winter and spring months. I have frequently watched their movements among the trees during the last few days, which gave me every reason, I thought, for simply asking if other apirians have found the birds to be destructive in the way I am about to mention. Our hives stand in the kitchen garden facing full south, so as to catch the morning sun, and to be sheltered as much as possible from the cold winter winds, which have been very trying lately for our little feathered and winged friends. No doubt Master Tommy has taken a greater advantage of the bees than he would have done if the weather had not been so severe; but at all events one does not come amiss with him at almost any time when he sees the way clear. He will soon be down on the alighting board, and as soon as poor Apis puts in his appearance he is immediately seized and carried off to the most convenient place, which generally proves to be the nearest tree. There are some small Apple trees close to the hives, and on examining underneath them I was surprised to find so many lifeless bees which had been treated in the way explained. I should be pleased to hear if any other bee-keepers have found the black-capped tomtit to be destructive in the way I have mentioned.—G. H. P.

members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (J. C.).**—Mr. Cole's work, the "Royal Parks and Gardens of London," can be had from this office, post free for 2s. 11d.

**Trap for Woodlice (G. F. B.).**—There is no better trap for woodlice than a boiled Potato wrapped in a little hay loosely, and placed in a small flower-pot laid on its side near their haunts. The woodlice will enter and feed on the Potato, remaining secreted in the hay, and being examined every morning they may be shaken into a vessel containing boiling water. This continued for a time will soon rid the house of the pests, having baits in proportion to the size of the house.

**Dendrobium nobile not Flowering (Idem).**—Growth in places of flowers is a consequence of the imperfect ripening of the pseudo-bulbs, the plants being kept at too great a distance from the glass and not having sufficient light with a reduction of moisture so as to harden them. As the growths reach maturity withhold the supply of water, removing the plants into a cooler and drier atmosphere, with full exposure to light and sun, in order to thoroughly ripen them. Water should only be given during the resting period to prevent shrivelling. A temperature of 50° artificially is suitable during the resting period. All that is wanted to restore their floriferousness is to secure a good growth and ripen it thoroughly.

**Peas for August (A. B.).**—You cannot ensure a supply of the best pods for exhibition in August from one sowing, because you cannot forecast the weather, and there is necessarily a considerable difference in the time in which Peas develop, according as the summer may be wet or dry, hot or cool. Telegraph and Duke of Edinburgh (which you name) we should sow quite at the end of April, making at least two sowings afterwards as the plants appear for affording pods towards the end of August. Evolution is one of the best Peas for exhibition at the time named, and is one of the most continuous bearers. It is large, dark, green pods.

**Roses for Church Tower (A. B.).**—You will obtain the most satisfactory result from the hardier kinds, such as Dundee Rambler and Ruga of Ayrshire, Crimson or Amadis, Blush, Elegans, and Inermis of Bour-sault; Madame d'Arblay of hybrid climbing, and Felicite Perpetue, with Williams' Climbing of the evergreen sections, William Allen Richardson (Noisette) is one of the best climbing Roses; fitting companion Roses are Reine Marie Henriette, Cheshunt Hybrid, and Gloire de Dijon, all Tea-scented. Passiflora cœrulea is the name of the common hardy Passion flower. Clematis are very fine, and associate well with Roses. Jasminum nudiflorum and J. officinale majus would be suitable. The finest of the Ampelopsis is A. hirsuta, A. Veitchii is very attractive, and A. sempervirens has evergreen foliage but not very hardy.

**Vine Roots Unhealthy (W. J.).**—Some of the roots you have sent are quite dead. We have no data to guide us as to cause. It may be the result of ungenial soil, or of the foliage falling prematurely last summer through drought, debility, or the attacks of insects. We assume they are in an inside border, and if so that may have become too dry. You have done right in giving liquid manure, also in removing some of the old soil and placing fresh in contact with the roots. Cover this with good manure by-and-by, so that the soil is kept moist; roots will then form near the surface, and can then be fed with top-dressings of fertilisers washed in, or liquid manure. The border must also be moist right down to the drainage. You cannot start the Vines too steadily. Disbud in due time, so as to prevent any interlacing of the laterals and overcrowding of the foliage, and the Vines will improve.

**Various (H. H.).**—Stout cuttings of the young growths of Hydrangea paniculata will strike in pots of sandy soil surfaced with pure sand kept moist, and the leaves fresh in a warm propagating case or hotbed have a temperature of about 65°. The cuttings must not be very soft. Perhaps a better plan is to insert cuttings of half-ripened wood under handlights in a shaded position in the garden in the summer. We should try the former plan in your case, inserting all the young growths except two or three at the base of each branch, cutting back to these after taking the cuttings from the parts above. You may give more root room to your Maréchal Niel Rose in the manner you propose now. We should also remove as much of the old soil as can be done without materially disturbing the roots, adding fresh turfy loam, pressing it down firmly. Give fertilisers or liquid manure after the plants start growing freely, never allowing the roots to get dry, yet the soil must not be saturated. Acacias are propagated by inserting cuttings of the young wood just when getting a little firm in sand under bellglasses in a temperature of about 60°. Quassia water will destroy aphides and it does not stain. Boil 4 ozs. of chips for twenty minutes in a gallon of soft water, then add three gallons of cold water, stir well, and it will be ready for use.

**Orchid and Gardenia Flower Buds Falling (W. J. C.).**—Probably you have kept the Orchids named too dry at the roots, and though at this time of year liberal supplies of water are dangerous, yet the other extreme is fatal to the flowers. Give them as light a position as possible, and keep the peat and moss well moistened; this may save those that remain upon the plants. The flower sent in the letter is too much crushed to be recognised. The Gardenias are suffering in a similar way, either because they have had a check at some time, or because the bottom heat is insufficient. They should be plunged in bottom heat that can be kept at about 80°, with an atmospheric temperature about 10° lower. If the plants are syringed twice daily the buds will develop quickly. If the pots are full of roots

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or

weak stimulants may be given, or better still, a little artificial manure applied to the surface. In the later batches the roots must be kept steadily growing, or the flower buds when they appear will be puny if not deformed. In the majority of cases the deformity and falling of the flower buds of these plants is due to inactivity of their roots and strong supplies of liquid manure during the time root-action is defective. Strong insecticides will also cause the same results when applied as the buds are forming.

**The Eucharis Mite (W. J.).**—The bulbs you sent are badly infested with "the mite," which you can easily find if you examine some of the others with a pocket lens. The best plan will be to turn all the plants out, turning the soil or removing it to a distance, and it must not be employed again for plants. Well wash the bulbs in a solution of softsoap and petroleum, 2 ozs. of softsoap with a little soda dissolved in a gallon of boiling water, and stir in very briskly while hot a small wineglassful of common petroleum, applying this as hot as the hand can be borne in it, rubbing it into every crevice with the aid of a soft brush. That has answered in the case of some infested bulbs, another cultivator having found a similar mixture of Gishurst compound and Fir tree oil efficacious, except when the insects eat quite into the bulbs. In that state they are beyond cure, and should be burned. Place them in rather small well-drained pots in turfy loam, adding sand and crushed charcoal to keep it sweet and porous, placing some of the latter in contact with the bulbs. Plunge the pots in a bottom heat of 80° to 85°, if convenient in a stove or pit having a night temperature of 65°, applying water cautiously and judiciously. When the plants are established they require copious supplies of water when flower stems are visible, liquid manure to support good foliage, and when this is fully developed a gradual reduction of water and a rest of six weeks or so. Then when placed in heat, they throw up another series of spikes.

**Good Florists' Flowers (Young Gardener).**—The following are all good varieties of their kinds, and will form excellent representative collections:—Twenty-four Carnations.—Scarlet Bizarres—Admiral Curzon, Fred, George, Robert Lord, Crimson Bizarres—Master Fred, J. T. Hextall, Harrison Weir, Thomas Moore. Pink and Purple Bizarres—Sarah Payne, Falconbridge, Squire Llewellyn, James Taylor. Purple Flakes—James Douglas, Dr. Foster, Squire Meynell, Mayor of Nottingham. Scarlet Flakes—Clipper, Sportsman, John Ball, Dan Godfrey. Rose Flakes—John Keet, Sybil, James Merryweather, Mrs. Lodwell. Twenty-four Show Dahlias—Chris. Ridley, James Cocker, Hon. Mrs. P. Wyndham, Henry Walton, James Vick, Goldfinder, Prince Bismarck, Joseph Ashby, William Rawlings, Alexander Crumond, Ethel Britten, Julia Wyatt, Ovid, Thomas Goodwin, Toison d'Or, Mrs. Henshaw, Paradise Williams, John Downie, John Bennett, John Standish, John Wyatt, Lady Goughly, Leah, Lord Derby. Twelve Bedding Dahlias—Rising Sun, George Thomson, Mont Blanc, Little Wonder, The Pet, Cloth of Gold, Dark Model, Flora MacDonald, Faust, Royal Purple, Prince Frederick William, Anzora. Twelve Pompon Dahlias—Fireball, Lady Blanche, Amelia Barber, Little Arthur, Prince of Lilliputians, Dove, White Aster, Crimson Beauty, Burning Coal, John Sandy, Louis Rodani, Triumph. Twenty-four Fuchsias.—Single Dark Varieties—Sir W. G. Armstrong, Lord Falmouth, Enoch Arden, Try Me Oh! Resplendent, Rev. T. Wiltshire. Single Light Varieties.—White Tubes and Sepals—Beauty of Trowbridge, White Souvenir de Chiswick, Covent Garden White, Marginata. White Corollas—Cannell's Gem, Delight. Double Dark Varieties—Avalanche, Sir Garnet Wolseley, Alpha, Prince Leopold, King of the Doubles, Extraordinary. Double Light Varieties—Mrs. H. Cannell, Kingsburyana, Miss Lucy Finnis, Marchioness of Anglesey, Edelweiss, and Chicago. Twelve Show Pelargoniums—Cicely, Artist, Purple Gem, Ruth, Prince Leopold, Virgin Queen, Charles Turner, Corsair, Despot, Meteor, Purity, Potentate. Twelve Ivy-leaf Pelargoniums—Madame Thibaut, Alice Crousse, Emile Lemoine, Abel Carrière, Jeanne d'Arc, Comte Horace de Choiseul, H. F. Barron, Josephine de Hohenzollern, Souvenir de Charles Turner, Rubens, Gloire d'Orléans, Viscountess Cranbrook. Twenty-four Picotees.—Heavy Red-edged—John Smith, J. B. Bryant, Brunette, Master Norman. Light Red-edged—Thomas William, Violet Douglas, Mrs. Bower, Elsie Grace. Heavy Purple-edged—Zerlina, Mrs. A. Chancellor, Alliance, Tinnie, Muriel. Light Purple-edged—Ann Lord, Clara Penson, Her Majesty, Minnie. Heavy Rose and Scarlet-edged—Mrs. Payne, Miss Horner, Fanny Hellen, Edith Dombtrain. Light Rose or Scarlet-edged—Mrs. Allcroft, Miss Wood, Nellie, Miss Gorton. Hybrid Perpetual Roses for Exhibition.—Marie Baumann, Charles Lefebvre, La France, Baronne de Rothschild, Louis Van Houtte, Etienne Levet, Alfred Colomb, François Michelin, Marie Rady, Madame Victor Verdier, Marquise de Castellane, A. K. Williams, May Quennell, Marie Finger, Star of Waltham, La Rosière, Général Jacqueminot, Duchess of Bedford, Duchesse de Vallombrosa, Mrs. Baker, Madame Lacharme, Sir Garnet Wolseley, Mons. E. Y. Teas, Magna Charta. Twenty-four Verbenas.—Lord Brooke, Striata, Distinction, Fairy Queen, Purity, Dr. Feyerlin, Queen of Verbenas, Reine des Roses, Delicata, Blue Boy, Ball of Fire, La Grande Boule de Neige, Warrior, Carminata alba, Burns, August Renz, Apollo, Baron Von Berchem, Edward Perkins, Flower of Dorset, Lord Cranbrook, Lustrous, Mabel, and Swanley Gem.

**Names of Fruits.**—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. (W. L. Bird).—Apples: No. 1, Newtown Spitzenberg; 2, Not known. Pears: 1, Bellesime d'Hiver; 2, Glou Morceau. The Fern is Woodwardia radicans. (H. Hewat Craw).—We believe your Apple to be Robinson's Pippin.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (Col. Trevor Clarke).—The one with bipinnate leaves is *Acacia dealbata*, the other with broad long phyllodes is *Acacia longifolia*. (Woodbine).—*Acacia dealbata*. (Hortus).—1, Apparently a member of the natural order Melastomaceæ, but the material sent was insufficient to determine what species it is; 2, *Erica barbata*; 3, *Gasteria verrucosa*. (A Young Gardener).—1, *Juniperus recnrya*; 2, *Thuja occidentalis*; 3, *Cupressus torulosus*:

4, *Æschynanthus pulcher*; 5, Cedar of Lebanon. (H. M.).—1, *Asplenium flaccidum*; 2, *Polystichum angulare*; 3, *Polystichum aculeatum lobatum*; 4, *Pteris cretica albo-lineata*; 5, *Asplenium bulbiferum*. (W., Reading).—Yes, your plant is *Oncidium dasystyle*, and is a native of the Organ Mountains, Brazil, whence it was introduced by Mr. B. S. Williams. In typical specimens the pseudo-bulbs are about 1½ inch high, elliptical, and the leaves 5 inches long by 1 broad.

## COVENT GARDEN MARKET.—FEBRUARY 24TH.

BUSINESS better, the improvement in Grapes being well maintained. Forced vegetables in demand.

## PROFITABLE FARMING.

In the first paper of this series mention was made of the fact that Sussex was coming to the front as a leading agricultural county, but among other reasons for this statement no mention was made of perhaps the most important of all—the Sussex Association for the Improvement of Agriculture, which, under the energetic leading of Major Sergison and the safe guidance of Professor Jamieson, has already done so much good work for the farmer by showing him clearly, not without much opposition, how to turn his land to best

account, and how it is possible to render it infinitely more fertile than it is under ordinary culture. The importance of the work of this Society can hardly be overrated. So remarkable are the results of the work done at the experimental stations that the process of cultivation, or rather the application of chemistry to practical agriculture which has been carried out, has been regarded as an entirely novel process. Yet Professor Jamieson has repeatedly assured all who would listen to him that he had no great discovery to explain, no new kind of manure to offer, hardly an improved process of cultivation, but simply the application of common sense to chemistry. The work of the Association is to find out what is wanting in the soil, to see how that want may be supplied economically, and to do it.

The writer has followed the working of the Association from the outset with keen interest, and has applied the lessons taught by it to practice with such success that he is convinced that not only have farmers generally much to learn, but that every county association of agriculturists must eventually seek for improvement in the same sensible manner. To the ordinary farmer agricultural chemistry is still a mystery. He has almost always been accustomed to use farmyard manure to impart fertility to the soil. Sheep-folding is a step in advance to which he is certainly also accustomed, but artificial manure has only been used by him as a mysterious mixture, and his conception of its composition and real value has been vague and undefined. It is doubtless owing to this ignorance that dealers in manures have thriven apace; yet one is really constrained to wonder how they can have possibly been suffered to gull the British farmer so long. When Professor Jamieson first published his formulæ of manure mixtures for farm crops we were told by dealers in special manures that the mixture for corn would, from its excessive quantity of nitrogen, induce such a free growth of straw that we should get very little grain, and the crops would inevitably go down before harvest. The result certainly did show an increase in the bulk of straw by from a third to a half, but it also showed a proportionate improvement both in the quantity and quality of grain. In the last report published about a month ago we are told of a crop of Wheat of 6 quarters per acre; of another of 8½ quarters per acre; of an extra amount of profit per £2 12s. upon an outlay of £1 10s. 6d. for genuine artificial manure. It was calculated that an increase of £4 per acre above ordinary profits was possible, as actual results showed clearly. Speaking generally, the results show that sulphur and magnesia are in all probability not required by plants, or that the quantities required are so infinitesimal as not to demand attention in practice. That lime is required, that potash is essential, and that phosphorus and nitrogen are not only essential, but seem to regulate the produce in a very marked degree.

But in order that the crops may derive full benefit from the application of genuine home-mixed manures the soil must be relieved of superfluous water by drainage. Next we require mechanical division. Such we find in perfection in what is known as good mixed soil, containing a liberal proportion of small stones; next thorough cultivation and freedom from couch grass and other foul perennial weeds, and then with an intelligent application of manures and timely sowing and reaping we may attain to the best possible results, and depend upon it they will be much superior to those following ordinary practice.

The writer has carefully used the manures recommended by Professor Jamieson for pastures, roots, and corn, and in every instance with excellent results. Perhaps the most remarkable of such results was the annual improvement of the pastures laid in for hay. Year by year did the bulk of the hay increase, and there can be no question that the benefit arising from the use of artificial manure is not a thing of a season. But then there must be a regular annual use of the manure, only a smaller quantity becomes necessary after the first two or three seasons. We have before now

told how we brought a seven-acre meadow from a state of comparative barrenness to one of high fertility by the use of pure artificial manures only. We can also point to arable land where we have grown three corn crops in consecutive years, each crop being better than the one taken before it. In a word, we have learnt how to dispense altogether with the most costly of all manures—that made in the farmyard; to use better, cheaper, and more powerful manures, and to obtain better crops under the teaching of the Sussex Association for the Improvement of Agriculture.

#### WORK ON THE HOME FARM.

Artificial manure is now being sown on the grass land, and we shall have no more sheep or cows upon the pastures laid in for hay till after the haying. To have a full crop of hay the grass must be thus reserved and grazing cease, otherwise the haymaking is retarded and the quantity reduced. See that fallen branches and all stones be picked off grass land before the bnsh or chain harrows and rollers are passed over it. We have met with incredible carelessness in so simple a matter as stone-picking, and seen the mowing machine broken and work brought to a standstill through what was plainly culpable negligence. Rye sown in autumn for the breeding flock will now have a hundredweight of nitrate of soda per acre, both to quicken and invigorate growth. We have a large breadth of Winter Tares, but fear we shall run short of green food, as we have not got a piece of Rye Grass to follow the Rye. Circumstances beyond our control prevented our having the Rye Grass, but we are nevertheless fully aware how much we shall feel the loss of it, and due care will be taken to set this matter right for another season. To follow the Winter Tares a piece of Spring Tares will be sown after White Turnips and Swedes as soon as possible, and successional crops of Spring Tares will be sown onwards till May or June. Never did we find Spring Turnips more useful both for cows and sheep than during the drought of last summer. We hope to have some forward batches of fat lambs, and like to finish some of them folded on Tares with trough feeding. On the whole the lamb crop is a good one, and we have a rather large proportion of twins. There is a considerable difference in size among them, but then that is not unfrequently the case among cross-bred sheep, and our cross is between blackfaced Suffolk ewes and pure Hampshire Down tups. The ploughs are in full swing, and the sowing of spring Beans and Peas is being done. Barley will follow, and then Oats. We shall sow a good white Oat upon our best land, and Black Tartarian Oats upon land that is being brought into good condition as fast as possible. A large stock of Oats and Oat straw is invaluable just now for all sorts of live stock, and a surplus supply of good Oats always obtains a ready sale. Inferior samples of Oats are by far too common in market. There is no difficulty just now in obtaining 23s. to 24s. per quarter for first-class Oats, and that is certainly a profitable rate for a good crop, apart from the value of the straw both for sheep and bullocks.

SUTTON' FARMER'S YEAR BOOK.—We have received a copy of this work, which has been recently issued from the press. Amongst its leading features are a calendar of farming operations for the year; illustrations, botanical descriptions, and uses for which they are most suitable, of the leading kinds of natural Grasses; an article entitled "The Grass Seed Industry," with illustrations, giving some details of the sources of supply, the selection, testing, detection or adulteration and other interesting particulars in reference to the various Grasses used in agriculture; also instructions in the cultivation of the several kinds of agricultural roots. It is worthy of the perusal of home farmers and agriculturists, to whom it is sent post free on application.

### CROTONS FOR DECORATION.

**T**HE groups of miscellaneous plants arranged for effect at exhibitions have probably assisted in causing the adoption of a more natural system of culture for Crotons. It was a common practice a few years ago to pinch the plants, irrespective of habit and variety, when a few inches high, to induce the formation of branches at the base, and lay the foundation of future bushes or pyramids. This practice is still prevalent, and in a very short time the plants subjected to such treatment become too large and are useless for most ornamental purposes. Certainly, when required for exhibition and association with large Palms, Ferns, and trained specimen flowering plants, well grown highly coloured plants are very beautiful; but the variety should be fully considered, or many will not display their true character to the best advantage.

It is not, however, my intention to write about these specimen plants, for there are hundreds of gardens in which they are of no service, and where it is only a waste of space and labour to grow them. When needed only for furnishing the house in which they are grown large bushes or pyramids cannot be arranged with other plants so effectively as smaller plants grown upright without topping.

Few plants, when their beautiful foliage is well developed and highly coloured, are more telling amongst other foliage and flowering plants than Crotons. For the dinner table or single vases scarcely any surpass them, for they are equally effective by gas and daylight. Some varieties, for instance the beautiful deep crimson Baron James de Rothschild, Newmannii, and others are brought out vividly by artificial light. Few plants last so long in good condition for such positions as Crotons. Certainly some are better than others, for the foliage, even in rooms where gas is used, clings to the stems for a long time—in fact, it will become dried upon them before it falls.

To have Crotons in good form for decoration the whole year round in various sized pots, cuttings should be rooted every month from now until the end of September. For finely developed plants to stand singly either in vases or for elevating above surrounding plants in groups, good heads must be rooted with large well-coloured foliage at the base. It is often impossible to get as many of these heads as are required, therefore side shoots produced after the head has been removed may be rooted and grown until they have developed bold foliage. For winter and spring decoration in 5 and 6-inch pots these will be handsome specimens 1 foot to 18 inches high.

Crotons do not root so freely now as during the growing season, for then any number of large heads may be rooted without losing a leaf. When large heads have to be taken off they can always be left until the plants are starting, and then cut them as near the top as possible to secure good foliage. Those who cut into the firm hard wood and think of rooting the head without losing the lower foliage, even

in the best appointed propagating frame, will be mistaken. The firm wood is twice as long rooting as that of a softer nature, and the lower leaves are certain to fade before the head is rooted, but when taken off where the wood is soft every leaf will be retained. Many fine heads are spoiled by carelessness in this matter at this as well as at other seasons of the year. Heads root freely enough at all seasons of the year if taken off where the wood is moderately soft and inserted singly in pots. Good sized heads are placed in 5 and 6-inch pots, and few in less than 3 inch, without they are required in very small pots for special purposes. In this case highly coloured side shoots are employed and rooted in 2-inch pots, and after they have been hardened are ready for the form of decoration for which they are required. The pots for cuttings should be drained and then filled with a compost of loam, one-seventh of decayed manure, and about one 7-inch potful of soot to each barrowful of soil, to this a little coarse sand may be added. Place a little sand in the centre of the pot for the base of the cutting to rest upon. Water and plunge them in the propagating frame or under handglasses, and keep them close until rooted. By plunging the pots and covering the surface of the soil with cocoa-nut fibre refuse or other material, evaporation is arrested and no more water is needed until roots are formed. Shade is necessary until the cuttings are rooted and able to withstand full light and sunshine afterwards.

To maintain a good number of highly decorative plants the whole year it is important to root a quantity of various sizes during August and September. These, if kept in a light sunny position in autumn, and wintered in a temperature of 60°, will continue highly coloured. These may be repotted at once, using the compost advised above, into 5, 6, 7, and 8-inch pots, according to their size and the variety of the plants. For such as *C. Chelsoni*, *C. interruptus aureus*, *C. Aigburthensis*, *C. Rodeckianus*, and others do not require such large pots as *C. Aneitense*, *C. Baron James de Rothschild*, *C. Johannis*, *C. Hanburyanus*, *C. Queen Victoria*, and *Prince of Wales*. After potting plunge the pots in sawdust, cocoa-nut fibre refuse, or any similar material. If this is kept moist and the plants liberally syringed they will fill their pots with roots before water need be applied to them. Syringe liberally twice or three times daily during bright weather when the season has somewhat advanced, twice being sufficient for the present. The plants can be well grown without plunging, but evaporation from the soil is greater, and the labour of watering considerable during bright weather, for they must never be allowed to suffer in any stage. I have never found it good for plants to be constantly pouring water into their pots to keep the soil moist about their roots. They are subjected to two extremes during every twelve hours of bright sunshine, for they are either dry or wet, but when the pots are plunged and the plunging material kept moist they only need occasional applications to keep the soil moist. These plants may be potted from time to time if larger specimens are required, but the size named is large enough for finely developed specimens, nearly all forms of decoration. These plants will by midsummer be in splendid condition for any purpose. Heads and cuttings rooted now will succeed them, and quantities should be rooted during the months of June and July, so that they can be had in suitable condition by autumn.

To grow highly coloured symmetrical specimens give the plants plenty of room, for if crowded they cannot be expected to be shapely. Employ no shade, but expose them to full light and sunshine and not too far from the glass. It is also important to keep them in a close moist atmosphere, when they will grow rapidly and colour their foliage as developed. While the plants are growing very little air is admitted, in fact the ventilators are never opened from October until the weather is sufficiently genial in spring to admit a small quantity of air without lowering the temperature or chilling the plants. Very little ventilation is given during the whole of

the summer, in fact none except when the days are very bright and hot. Under this treatment there is no fear of the plants burning provided they are allowed sufficient water at their roots, the atmosphere is kept moist, and they are freely syringed. When these conditions are observed rapid growth is the result, and insects such as thrips and spider will not trouble the plants.

At any time from the present until October, when the plants have developed large highly coloured foliage and further growth is not desired, the plants may be gradually hardened to cooler treatment. This will prevent further growth, and keep them for a long time in the best condition for decoration. Before plants are employed in rooms or for exhibition harden them carefully on these principles, or their foliage will flag and perhaps not recover in cool quarters. All plants intended for the winter ought to have their growth completed and be highly coloured by the end of September, for growth made after then cannot be well coloured. When the pots are full of roots feeding may be practised, supplying either clear soot water or artificial manure to the surface of the soil.

The varieties of Crotons are now very numerous, and the majority are ornamental when full grown. The following are useful sorts, in addition to those already enumerated:—*angustifolius*, *Disraeli*, *Lord Derby*, *Evansianus*, *Hawkeri*, *majesticus*, *Mortii*, *Princess of Wales* when well coloured, *Sinitzinianus*, *variegatus*, *picturatus*, *Warreni*, and *Wiesmanni*. Crotons that it is desired to push into growth as quickly as possible should be placed in a night temperature of 65° to 70° after they are potted.—DECORATOR.

### NOTES ON PEAS.

MUCH has been written in these pages of late respecting this very important vegetable crop. The cultural notes by Mr. H. Marriott will have been read by many with much interest, as it is well known that he is one of the most successful Pea exhibitors in the country. One year, however, I had the satisfaction of surpassing his best collections at South Kensington. I have not had time to grow for exhibition since; but I still cultivate large quantities for the kitchen, and so long as I receive the "well done" of my employer the showing is a secondary consideration. Mr. Marriott is, if I may use the expression, a Pea man. He has himself to please, nobody else, and Peas are his hobby. If this does not account for his prizetaking it will, I think, for the time and expense he devotes to their culture. The treatment they receive from their youth upwards in watering, clipping, thinning, shading, &c., must indicate to many hard-working gardeners how hopeless is their chance of winning any Pea prizes if all this is necessary.

In my opinion prize Peas may be produced with less attention than many think. I have never at any time sacrificed the kitchen supply to win a prize or compete at any show; but if abundance can be had for the kitchen and a few for exhibition from the same row everyone is satisfied. Our plan has always been to sow in rich soil and produce strong plants of a prolific and lasting character, and only a stem here and there was treated for show purposes. This was any one which appeared extra strong or had formed extra large pods; then some small ones on the same stem might be cut and the point taken out of the main leader. This had the effect of making the pods remaining swell to their fullest extent and become excellent for showing. The summer before last I exhibited a few dishes very successfully, and they were gathered from rows which supplied the kitchen at the time, and from which we saved many quarts of seed afterwards.

Peas will always pay handsomely for liberal cultivation, such as deep digging and copious manuring; and when this is done at the first good pods will be produced in spite of everything. I do not object to Mr. Marriott growing his Peas in the way he thinks best, but what I like to see and encourage is a competition of produce representing the general merits of varieties. Good Peas or show pods will never be produced in poor soil, and this should never be forgotten when sowing is going on. Last year we had some exceptionally dry weather in July and August, and it was a most difficult matter to keep the Peas fresh and green, and the conclusion we came to was that midsummer Peas as a rule are sown too near the surface. Watering and mulching are partial remedies for this; but when the soil becomes hot and quite dry for several inches down it is difficult to save the roots from its injurious influence if they are only 2 or 3 inches from the surface. The trench system of growing Peas is one

which cannot be overpraised, but many seem to forget that Peas sown in March are those which will be liable to suffer from drought and heat in June and July, and the sowing in trenches is often not begun until it is too late. I am in favour of throwing the trenches out 1 foot in depth, placing 3 inches of good manure at the bottom, 2 inches of soil over this, sow the seed, and cover with 2 inches of soil. The roots will soon find their way into the manure, and when the hot weather comes they will be 1 foot below the surface; and in earthing up or mulching it is an easy matter to fill the trench level with the surface of the soil. All Peas sown after the beginning of March should be treated in this way. Late crops are also benefited by it, as, although there may be plenty of moisture when they are in pod in late September and October, it is the drought of July and August which is apt to check the growth of the plants and reduce their cropping qualities further on. Let it be understood, however, that it is only from March that I recommend trenches in a general way. We have had several rows of Peas, more particularly the wrinkled sorts, fail altogether by being sown in trenches in January and February, and in wet localities or cold stiff soils early sowing in trenches should be avoided.

Wrinkled Peas are assuredly the most tender, and the instance of sowing Wordsley Wonder the first week in January to secure pods for exhibiting on the 14th of July, as cited by Mr. Marriott (page 134) indicates how wrong it is to have a Pea buried in the soil for two months at least that are decidedly against its advancement. In the summer of 1884 I won a prize with Wordsley Wonder at South Kensington in July, and the seed was not sown until the 14th of March—ten weeks at least later than Mr. Marriott's. It is a rule, almost without an exception, that during the growing season, which extends from the beginning of March onwards, all Peas will be ready for gathering in sixteen weeks at most after sowing, and I would guarantee to sow any kind of Pea on the 14th March and exhibit it in prime condition on the 14th of July. In all my experience of Wordsley Wonder I have never dreamed that it took upwards of seven months to gain maturity, and I am sure this is not its general character.—A KITCHEN GARDENER.

### CHRYSANTHEMUMS AND THEIR CULTURE.

(Continued from page 127.)

#### TRAINING PLANTS FOR PRODUCING LARGE BLOOMS.

VARIOUS are the methods of training Chrysanthemums for the production of large blooms. In referring to the different systems practised, my remarks will be strictly confined to those plants which are grown specially for supplying large blooms either for exhibition or home decoration, not to trained specimen plants. Some growers top the plants when 4 inches high, the point of the shoot being pinched out. This induces the production of two shoots, which are tied to a stake and allowed to extend till the first natural "break," and from this break two other shoots are carried up. Some persons consider this topping induces a dwarfer habit, but that does not always follow, as I have seen plants grow quite as tall when treated in this manner as when grown under other systems. Other cultivators top the plants when 8 inches high; three branches are produced after this topping and trained to separate stakes, all axillary growths being removed as fast as they appear. Flowers produced by this method are generally large, but owing to the wood not being thoroughly ripened, consequent on the late topping, and the growths being behind their natural stage, are not of first-rate quality, lacking depth and solidity. In order to reduce the height of their plants some growers in the early stages starve them by withholding water—giving much less than they properly require, and also by allowing them to become root-bound previous to shifting into larger pots. Flowers produced by such plants are rarely of the first order of merit, having the defects mentioned in the previous case. A plant rendered constitutionally weak by starvation cannot produce perfect flowers.

Many plants are grown with one stem only, not topping them at all, but allowing them to attain the customary height of each variety. All other conditions being favourable good flowers are produced by such plants, but I consider the practice wasteful, as one plant will produce more flowers of equally good quality. It moreover often happens that the points of the shoots are broken by winds, rain, and frequently by birds alighting on the points. When such accidents befall single-stemmed plants, they may be, and often are, spoilt, the time and attention bestowed being then wasted. I must make an exception in the matter of topping in favour of *Eve* and its sport *Mabel Ward*, which is the exact counterpart of its parent in growth. Good examples of these are seldom seen. The best way to insure good flowers is to grow the plants with one stem till the middle of May, then top them, select three of the best shoots resulting, from these three branches rub off all

side shoots as fast as they appear, and "take" the first buds produced, which are early "crowns." As a general system it is best to allow varieties to assume their natural habits, the growth is then solidified, and all the wants of the plants met at the proper time. The plants are not topped at all, but allowed a free uninterrupted growth until the first natural break, which sometimes occurs about the middle of May or early in June, according to the time cuttings were struck early or late. Some varieties are earlier in their first stages of growth than others, and some, notably Madame C. Audiguier, grow 4 feet high before they break, while some others do not grow more than 1 or 2 feet high before the first bloom bud is formed. No absolute rule can be laid down as to the time of the first natural break; when it does occur the bloom bud must be rubbed out, and three of the strongest shoots selected. These must be securely tied to a stake as they grow, and as fast as side branches are produced they must be taken off, retaining only the three shoots selected at the first break. At the point of each branch flower buds will form in due time, commencing early in August and continuing throughout September. Until the buds are selected which are to produce the best flowers all other buds and branches must be taken off as soon as this can be done without damaging the stems or points of the main shoots, thus concentrating all the energies of the plant to the three stems as selected at the first break.

#### STANDARDS.

Chrysanthemums grown as standards are useful for the decoration of the conservatory when placed in suitable positions on the floor. They are not so frequently grown in this form as in others, owing to the time and attention they require, and also because many do not approve of such close training as is required to produce the specimens. The varieties specially adapted for growing in this form are not numerous, the incurved section being most suitable, and I give the names of some of the best. For the production of good standards the strongest cuttings should be selected early in December, and struck in the manner that has been previously recommended. In all stages great care should be taken that they do not become drawn up weakly. As soon as the plants are well rooted, shift them into larger pots and place them in cold pits or frames. When all fear of frost is past—which in the south of England is usually about the second week in May, and in the north towards the end of the same month—care should be taken to place them in such a position out of doors that a light covering can be thrown over them should frost occur, which would otherwise seriously cripple the points of the shoots.

About the 1st of June they will require their final shift into 11-inch pots, using the same kind of soil as before advised. The position selected for their summer quarters should be thoroughly exposed to the sun and air, but sheltered from east and south-westerly winds. Plunge the pots about half their depth in ashes, which keeps them firm and the roots cool during a hot summer. Exercise great care to prevent their being blown about in windy weather, as the roots are easily damaged by the continual rocking backwards and forwards of the plants. Three stakes firmly driven into the ground in triangular fashion, and connected to the stake in the pot, is a good system. Only retain one stem, and when this reaches the desired height—3 feet, or 3 feet 6 inches—it should be topped. If the plants grow to this height before making their natural first break, so much the better; but if a break occurs earlier the shoots must be reduced to one, which is allowed to grow till the necessary height is reached. The topping induces other side shoots to form, which make the foundation of the future head. Reduce these shoots to four, and when these have grown 6 inches long again top them, continuing this process till the requisite number of branches is obtained to cover the trellis; but topping should not take place later than the middle of June. The number of flowers each plant is expected to produce must guide the cultivator as to the number of times the shoots should be topped; it is a mistake to attempt to produce too many blooms on one plant. It is far better to limit the number, and have them of better quality. Plants of the small varieties of incurved kinds, such as Mrs. G. Rundle if the heads are grown, say, about 2 feet in diameter and about 1 foot 4 inches in depth, fifty blooms will be enough; but in the case of White Venus thirty flowers on heads the same size would be ample. Of course, the plants can be grown much larger, but it should be remembered that the greater number of flowers the smaller they will be.

The shape the plants are to assume must be determined, and the sizes I have given answer very well if the form is convex. Bend pieces of strong galvanised wire of the length named over, fastening each to a circular ring as the foundation, and securing all to the top of the centre stake. Fix the framework from the bottom wire to the centre stake with the aid of two pieces of stout wire stretched across from one side to the other, as this prevents

the head swaying about. Commence training the branches as soon as they are long enough, as the foundation is more easily formed at this stage than when the shoots are longer and harder. When the bloom buds are formed, which will be early in September, disbud to one on each branch, and when they are swelling give the plants their final tying, as the shoots which are bent have plenty of time to right themselves; in this way severe training is not so easily detected as it is if done a few days before the plants are in bloom. Supply them freely with water at the roots during summer and at all times, and in the evenings of fine days freely syringe the foliage. As feeding the plants will be specially dealt

Fig. 28.—Standard Pompon Chrysanthemum.

with later on, it will not be necessary to dwell upon that point now. House the plants, and treat them the same as those grown for other purposes.

The varieties I have found best for the purpose are the following:—Mrs. G. Rundle, Mrs. Dixon, George Glenn, Aureum Multiflorum, Julia Lagravère, Venus, White Venus, Mrs. Haliburton, Prince of Wales, Dr. Sharpe.

Several varieties may be represented on one head if required, by grafting. Skilfully trained examples are occasionally seen in which blooms of the varieties are shown in concentric circles—the lower tier, say, Mrs. Rundle, the next Prince of Wales, then Mrs. Dixon, Venus, and George Glenn, with a central terminal flower of say

Princess of Wales. Some of the best specimens of this nature have been exhibited at Walton-on-Thames, and the method of grafting has been described as follows by Mr. G. Masters:—

"If plants are wanted with stems  $2\frac{1}{2}$  feet high growth should be encouraged until the plants are 3 feet in height, then pinch out the tops; leave about six eyes at the top to form the head, removing the others. When the top shoots have grown about 6 inches cut them off 2 or 3 inches from the stem; then take cuttings (scions), cutting the ends in the form of wedges, and insert them in the severed shoots of the prepared plant, securing them with wool or bass. Keep the plants in a cool house, and sprinkle and shade them until the union is effected, when they may be removed to the open air. Grafting may be done as soon as the plants are ready, which ought to be by the middle of May, so that the grafts can be stopped two or three times and thus form a fine head. It is important that the plants are in a healthy ree-growing state when they are grafted, and that the work be done quickly yet carefully. Care should be taken to graft varieties that flower as nearly as possible at the same time. Every shoot may be grafted with a different variety if desirable."

Pompons are well adapted for standards, and are excellent for both exhibition and home decoration. The method of training is often too formal to be agreeable, the growths being closely tied down, showing the bending and lacing of the stems, which should never be visible. Mr. J. Lyne of Wimbledon has made a welcome departure from the lacing system. The method he adopts in forming the heads is to continue pinching the shoots as soon as two leaves are formed till the 31st of July, then let them grow as they will. The result is seen in the annexed engraving (from a photograph), the plant represented being grown from a cutting inserted early in March; but as a rule Mr. Lyne recommends their being inserted in December. The varieties found suitable for this purpose are Rosinante, Dick Turpin; White, Golden and Lilac Cedo Nulli, St. Thais, James Forsyth, Madame Marthe, Golden Madame Marthe, Sanguineum, Souvenir de Jersey, Bijou d'Horticulture, and Lili-pupian.—E. MOLYNEUX.

(To be continued.)

#### FISH POTASH MANURE.

HAVING used this manure rather extensively during the past season. I have great pleasure in endorsing "J. G.'s" remarks on it (see page 134). Unlike "J. G.," however, my applications of it have been exclusively confined to pot culture, such as Vines, Pines, Figs, Melons, Tomatoes, Peaches, &c., and with highly satisfactory results, especially Vines and Peaches. The former carried and finished splendidly from six to eight bunches each, and was much admired by all who saw them. The Peach trees not only finished excellent crops, but carried their foliage healthy till late in the season. It was also noticed during stonion time not a single fruit fell. I may add, all our Peaches and Grapes under pot culture are finished by the first week in July, beginning as early in May as we can get them. I find our first Peaches were gathered on May 8th last season. So we have to start when the weather is anything but favourable.

To our permanent Vine borders we add manure annually, when we do so again we will bear in mind Mr. J. Gibson's remarks and use a little fish potash. To those who are about to try this manure for the first time, I would remind them a little goes a long way. For pot Vines we find about a pint to a 12-inch pot is ample without the addition of any other manure whatever. We have so treated a lot of cut-backs, which in due time are to come in for early work. In our trials of this manure before its general application we killed by an overdose several plants, others of the same kind being greatly benefited by a lesser quantity.—T. W. B., *Elstead*.

RENOVATING VINES.—"J. G." (page 134) gives his experience of the value of Norwegian fish manure for Vines and other plants. I can fully endorse all that he advances in its favour for Grape-growing, having seen Vines such as "J. G." describes restored to the rudest health in a remarkably short space of time, but it must be admitted that several other important matters, such as careful ventilation and watering, were strictly attended to, otherwise fish or any other artificial or natural manure would not have worked out such an improved state of health. I have used a good quantity of this manure in the vegetable garden at all seasons of the year, but its effects are not so distinctly seen during the summer as in the spring and autumn months, as at that season the ground appears to be often too dry to bring out its qualities sufficient for the use of plant life.

Last season some late Queen Broccolis were planted on firm ground and watered daily, but the drought was so severe that these plants could make no headway against it, and seemed to become smaller rather than grow. We were almost disposed to pull them up in despair, when the fish manure suggested itself, and we resolved to give them a trial. A quantity was mixed with some ashes strewn thickly over the ground, and slightly dug in so as to place it more within reach of the roots of the plants, and also to break the surface to allow a freer circulation of air and water. The results of this experiment are that we shall have a good number of heads to cut when other Broccolis are becoming scarce. Where small patches of ground only have to be dressed it is necessary to mix the manure, owing to its dry and dusty nature, with some damp material,

such as fine soil or wood ashes, otherwise a large per-centage will be carried away by the wind.

For potting purposes it is useful, Tomatoes and Strawberries especially being very partial to it, the roots being quickly attracted to the surface of the soil when an occasional sprinkling is given. We are about to use a quantity for dressing a large tennis lawn which is in want of some stimulating material, and I believe it will have the desired effect.—S. B., *Newbury*.

#### THE CYCLAMEN.

THIS plant has now become most deservedly popular, and I am of opinion that of late years among flowers very few have been more improved by hybridising and selection. If a packet of seed is purchased from a reliable source it is safe to say that 80 per cent. of the plants will produce flowers quite up to the standard for ordinary decorative purposes, so that if a few plants are raised at different times and a selection made of the best a beautiful and choice collection can be obtained.

Now is a good time to purchase and sow the seeds in order to have the plants in flower next year at this time. Twelve months ago I sowed a packet of seeds, and the bulk of the plants are now in bloom, and are giving great satisfaction. I sowed the seeds in a pan of well-drained sandy loam, covering them to about twice their thickness, press the soil down firmly, cover them with a layer of moss, water well, and place them in a Cucumber house or frame. The seeds are some time in germinating. This arises from two causes; in the first place the seeds are hard, and when they begin to germinate a small corm is formed, from which the leaves spring, and rooting commences at once. As soon as the little plants are large enough to handle they should be pricked off an inch apart into pans or pots, using sandy loam as before. Gently water and shade them for a few days if necessary, but do not keep them in too hot a temperature; about 60° is sufficient. They will grow slowly, but in time will throw up three or four other leaves, according to the swelling of the corm. When these have grown sufficiently each one must be taken up carefully and put singly into thumb pots, drained properly with finely broken drainage, using this time one-third sifted leaf soil to the two of loam and sand. Pot only moderately firm, for the roots are yet very tender and but just cover the corm. When they become established there move them to a shelf near the glass in a vinery at work, as the temperature of the Cucumber house will be too high, and induce the leaves to run up at the expense of the corm, and cause them to become stunted.

As soon as they are well rooted they will need a shift into large 60's, using soil mixed as before, but only just cover the corm. Examine them often in the matter of watering, for they will not thrive if over-watered. They will soon be rooting well into the new soil and the corms increasing in size, although the foliage will not show much sign of that. The usual ventilation given to the Vines will suit for the present. Look out for green fly at this stage, which attacks the under surface of the leaves, and apply the usual remedy. Red spider is an enemy they are subject to, and daily syringing will be necessary. When the plants have rooted fairly from the last shift put them into 48-size pots, and some of the best will need small 32's. The soil now must be different, as it will not be necessary to pot them again before flowering. I have found the following proportions to answer well:—3 pecks of turfy loam partly decayed, with silver sand added according to its condition, 1 gallon of dried cow manure sifted through a sieve of quarter-inch mesh, and 1 gallon of charcoal dust. Mix it well with the hand. Pot them firmly this time, leaving just a sight of the corm above the soil. Water well and return them to the same place. After they become established here the time of year will have arrived when they can be plunged in coal ashes in a frame not more than a foot from the glass. Give them sufficient room so that the air can pass freely amongst them, and a little can be left on at night when the weather is warm; but at all times a good growing temperature must be kept up. They will be found to do well in this position until they are taken in the houses, which will be about September, and after this time they will appear to cease growing in the foliage, excepting that of getting larger and thicker; but in reality the corms are hastening to maturity and storing up material for flowering. Soon the minute flower buds will be seen at the crown of the corm, and at this time and through the winter water must be given sparingly but judiciously, for if too much is given the flower buds die, and if too little the flowers come small and sometimes deformed.

By the end of the following January, if all has gone well, most of the flower buds will be rising above the foliage and showing colour. This will be a good time to introduce a few into a little higher temperature if wanted early, otherwise they will gradually come into bloom and last a long time. Their handy size and bright colours with a neat compact growth renders them a most useful class of plants for various modes of decoration. In looking over my

plants to-day I find the number of flowers range from fifteen up to twenty-eight on a plant, which I consider a fair number for my purpose. I once divided a hundred plants into four equal lots, and tried an experiment with a different mixture of soil for each lot and carefully noted the results, but the most satisfactory were the plants grown in the compost stated above.—THOMAS RECORD.

#### NEW v. OLD VARIETIES.

I FOR one, and I doubt if there are not many, who do not agree with "A. L. G." (page 134) as to old varieties being altogether superior to new. There are undoubtedly many old varieties of vegetables that are very difficult to surpass; still, if all were of the same opinion as "A. L. G." gardening would certainly become very tame, as novelties are often the greatest interest of the garden and gardeners generally. I would not pretend to advocate an excess of novelty in the vegetable list, as it would prove a too expensive indulgence, but they may profitably be patronised in moderation with advantage to both gardener and employer alike. Brussels Sprouts are, says "A. L. G.," represented by Aigburth only. This is a variety pretty generally discarded, and better varieties are substituted that prove more profitable. Reading Exhibition or Gilbert's Universal are to my mind far before Aigburth. A new form of Beet was grown last year, and which gave such satisfaction at the table that the same has been ordered this year.

Broccoli is a vegetable that has been much improved of late years, and the same holds good respecting Celery, Tomatoes, Turnips, and Peas, the latter especially so. Chrysanthemums, too, have had many valuable additions of late years. This is indisputable, more especially in the Japanese and early-flowering section. With regard to Melons, these are most numerous, and oftentimes very perplexing, as so many forms are sometimes produced from one packet of seed. It would appear that tastes differ more with Melons than with almost any other kind of fruit, some preferring scarlet-fleshed kinds and others green. With us last year Eastnor Castle, among others, was grown, and is often justly considered excellent, but I am under orders not to grow it again. W. Tillery and Blenheim Orange are varieties if obtained true are difficult to surpass for productiveness and quality, and represent a good type of green and scarlet-fleshed kinds.—S. B.

YOUR correspondent, "A. L. G.," I fancy to a great extent misinterprets the true meaning of Mr. Molyneux's advice, for doubtless he is one of the very first to view and try any new variety.

"A. L. G." ought by all means to have named the whole of the vegetables he finds it most economical to grow; in that case readers might have been able to trace how many are grown that were not long ago novelties or new varieties. Among the few penned I notice three. It may be "A. L. G." does not grow those new varieties until they have been well tried, but a nervous policy in looking on until the ice becomes cut up by others is not to be admired. That there is annually a vast number of doubtful novelties in the pages of most catalogues cannot be denied, and that many firms sell the same strain under different names is pretty certain. If they are good not much harm is done by that. It is certainly in the interest of seedsmen to supply the most useful and productive varieties even in made-up collections. I very much admire the terms exhibition and profit, as employed by Mr. Marriott. It may safely be predicted what position a collection of vegetables would occupy provided some of the new and old novelties were left out.

I remember a remark penned by "A Thinker" in a paragraph some time ago, that employers are pretty much as gardeners make them, or something very similar to that. I thought at the time what a weight of truth the short sentence conveyed. I could name an employer who not very many years ago complained that £3 in Pea seed alone seemed rather extravagant, having usually run on the 1s. to 1s. 6d. per quart line to short of £1 10s. Regarding the next season, nothing was said except a wish to have a supply of Peas equal to the preceding; the seed account with a few sundries having reached £8. The same employer, a very economical and thoroughly business gentleman, asks what sum will be required for Peas this year. "Nearly five pounds, sir," was the reply. "Quite right, well spent money that." The seed bill scaling £14 is paid by return without a murmur. Will readers pardon my details? I hope they may be of service. May I ask "A. L. G." how this employer's interest could have been better studied. Still I would say to any other young gardener, Take especial pains at all times and in all things to meet the wishes of your employers; but this does not imply that narrowing down to the lowest point in everything is most economical. Often a little careful and unassuming explanation with steady progress is more satisfying than rigid economy with bare results.

While I find it needful to keep a garden in pleasurable and profitable order with the least possible outlay, give me high-class men well paid, high-class seeds, and abundance of high-class tools.—LATHYRUS.

#### HARDY PERENNIALS AND ROOT-PROPAGATION.

AT the present time many persons are growing hardy perennials who seem little acquainted with the means by which they may be increased. One of the least-known methods perhaps is that of root-propagation. It has an advantage, too, as by root-propagation many good plants may be readily increased which are either slow to produce cuttings or do not flower sufficiently

early to produce seed. Another gain we find by root-propagation is that it is best done when the plants are in a dormant state, the best time being during the first three months of the year, though I have with such plants as the Japanese Anemones continued to insert quantities of rootlets till late in March. Some plants are so floriferous that it is almost impossible to obtain growth cuttings, in which case root cuttings are of still greater value. The genus *Gaillardia* affords an instance of this, as the plants continue producing flowers till cut down by autumn frosts. But some may urge that the *Gaillardias* are so free to produce seeds that these would more than compensate for the loss of growth cuttings; but supposing in a bed of *Gaillardias* we get some very fine forms, then root cuttings are of great value. In this way some years ago I secured a batch of a very fine *Gaillardia* which was at least 4 inches across, and which was considered entitled to the name afterwards adopted of *grandiflora maxima*.

The operation of root-propagation is not one of considerable difficulty, but on the other hand, may be performed by anyone having a fair knowledge of the plants themselves. The chief points to be observed are as follows:—The plant may be lifted and some of the larger roots detached, at the same time taking care to label them correctly, replant the specimen, but take care not to permanently injure the plants operated on, and it is best to cut the root its full length, which will give several cuttings. The next thing is to cut the roots into lengths of from 1 to 2 inches, laying them in one direction, so that they may not become reversed before placing them in the soil. Pots or pans may be used. I prefer pots well drained, and place the cuttings round the interior. When inserting the cuttings, leave the top visible above the soil—that is, for thick fleshy roots. Twiggy or fibrous roots I prefer scattering thickly in boxes or pans. Any ordinary soil will do, making it rather sandy; in this way continue till the work is completed. When this is done the pots should be removed into slight bottom heat. The boxes may be placed under the stages till signs of growth appear, and then place them where they may receive more light.

It now remains to enumerate those genera which can not only be propagated freely in this way, but which pay for the trouble. Taking them in alphabetical order, we first notice the *Acanthus*, which constitute one of the stateliest groups of fine-foliated perennials suited either for the rockwork in prominent positions, the specimen border, or for exhibition purposes. The whole of this group is easily increased in this way, and make saleable plants in less time than seedlings; the roots are large and fleshy and soon break into growth. The most distinct are *A. candelabrum*, *A. longifolius*, very handsome, and *A. spinosissimus*.

*Anchusa italica* forms a pyramid some 3 feet high and in diameter. This is also a free seeder. In some winters I have seen it killed, as far as the top is concerned; at such times I have had recourse to the roots, which dive deeply into the soil, and by lifting a few of these good flowering plants were secured for summer, and which, had the plant been left to itself, might have taken a full season to recover.

Amongst the most important of hardy plants which furnish gardens with flowers from very early spring till quite late in autumn are the *Anemones* or *Windflowers*, the majority of which are tuberous, therefore it is not to these that I now refer. Such species as *A. pulsatilla*, *A. alpina*, *A. sulphurea*, with all the forms of *A. japonica*, may be increased in this way; in the latter case it is decidedly the best mode, as every particle of root will grow.

*Doronicums*, *Echinops*, and *Eryngiums*, the former valuable for some of the early-flowering species which it contains, and the two latter equally valuable for picturesque planting on rockeries and the like, may be similarly treated. The *Gaillardias* are highly valuable free-flowering perennials, and which continue to produce flowers till frost comes. The roots of these are white, the older ones woody in the centre, and the latter do not break so readily as the younger and more fleshy. Then comes the fragrant *Jaborosa integrifolia*, a dwarf plant, preferring a sunny position; it is still uncommon and produces its large white tubular flowers from amidst abundant foliage.

In the *Oenotheras* we have some free seeders and others which can be propagated freely by cuttings and division; still it may be well to remember that *O. macrocarpa* and *O. missouriensis* may be freely increased by root cuttings. These two forms appear to be identical, at any rate what I have grown under the names. The showy *Poppies* of the Orient, *Papaver orientale bracteatum*, and allied forms, are not good to divide, for their roots run deeply and are very brittle, but by digging up the roots they may be had in plenty.

The next most important group is the *Primulas*, but considering their free-seeding qualities, and the ease with which seedlings of the species are obtained, I prefer to rely upon seeds,

the only one of which I always secure roots when opportunity offers being the old double crimson or Pompadour, *P. acaulis rubra* fl.-pl., a charming flower, but, alas! a short liver in England. It does better, however, in the northern than in the southern counties, though I have had it in fine condition close to London. I remember planting about 200 of this some years ago in the north which did splendidly, very much surpassing my most sanguine expectation. I planted them in a shallow frame somewhat below the ordinary level. They were, in fact, deluged by heavy rains, and evidently in perfect enjoyment of their temporary immersion; the soil was very rich, and contained about one-half well-decayed manure. I put some lights over them, indulged them to all warm showers, and very carefully protected them from both sun and frost. In the height of their growing season I watered them with liquid manure twice or thrice weekly. Here they grew amazingly and made grand tufts.

The finest of the *Senecios* is *S. pulcher*, which, contrary to its tribe, is a shy seeder, but which breaks uncommonly free from root cuttings; it deserves every encouragement, as it is among the best of autumn plants. *S. japonica*, syn. *Erythrochæte palmatifida*, is a very fine-foliage plant too seldom seen, and which in specimen form is unique.

The *Statice*s are all useful and good, in this case root cuttings make plants far more quickly than seeds, and it may be well to state that the more tender species, such as *S. Holfordi*, *S. profusa*, and others, do equally well. Then we pass to *Stokesia cyanea*, a plant which opens its flowers too late for outdoor culture in many parts; it well deserves greenhouse culture in these cases and can only be readily increased in that way. This completes the list of the most worthy; others there are, as *Symphytums*, but which are easily increased in other ways, beside which there are numbers, such as *Asters*, *Achilleas*, *Harpalum rigidum*, and many more which produce stoloniferous growths so abundantly as to need keeping in check. These I have avoided, deeming it sufficient in my present note to refer to those which for the most part do not exhibit any tendency to break unless assisted in this way. The plants may, when sufficiently strong, be potted and treated similarly to seedlings till well established and ready for placing out.

In my notes on page 74, second column, first paragraph, read "and is rarely detected save by the plants dying."—J. H. E.

#### THE ROYAL HORTICULTURAL SOCIETY'S PROVINCIAL SHOW.

I CONCLUDED from your leader on this subject that the "Royal" and Liverpool Association had agreed to work together to render the provincial exhibition a splendid success. I was sorry to learn to the contrary—that is, that the Association were going to hold their show as usual. This is confirmed by a letter from a friend who knows some of the Committee. I think this is to be regretted, for much local support, especially as far as the exhibits are concerned, will be centred in their own exhibition. I think it is a great pity for both that suitable arrangements could not have been made and the Association's show abandoned for one year, so that every chance would have been given the "Royal" to have proved a success. The Liverpool Association has done well since its commencement, but whether the Liverpool public are a flower-loving people remains in a measure to be proved. The very reverse seems to be the case, if I judge rightly, from the reports of this Association that have from time to time been sent to me. At most of the shows there appears to have been much less public patronage than would naturally be anticipated for a large city like Liverpool. The Association would have failed long since had it not been for the splendid subscription list they have obtained by the aid of honorary and ordinary members, and I hope that the subscription list will be increased and the Society's influence for good extended in a wider field than has been the case up to the present. I am, however, afraid that if the Association holds their show as usual in Sefton Park they will enjoy less of the public patronage this year than in the past. The Shipperies will be the centre of attraction, and all that come from a distance—I mean horticulturists—will try to put in an appearance to see the Royal at the same time.

If the Liverpool Association has not announced publicly their intention to hold their show as usual, I hope that they will offer the "Royal" a sum to admit their subscribers, and render them all the help in their power to make the provincial society a thorough success in every way.—HORTICULTURIST.

#### RABBITS INJURING FRUIT TREES.

"W. A. K." will find that rabbits and hares will not eat the bark from trees if they are simply washed with limewash about 2 feet up the stems. We have here an orchard about three acres in extent in which rabbits are enclosed with wire netting, and previous to the severe weather lately experienced the rabbits commenced barking the stems very severely. I was rather put to my wits to know what best to do. I at last thought of limewash, and had them at once done, and since that no bark has been eaten from any of the trees although there is a large number of rabbits enclosed, and they could get but little besides a few

Cabbage leaves when the snow was 6 inches deep, but how permanent this may be I am at present unable to say, but I am of opinion that if done annually it will be all that is needed for the safety of the trees.—W. A. WALTER.

SEVERAL letters reach us just as we are going to press describing the extremely WINTERLY WEATHER that prevails in various districts. The snowstorm appears to be general, but the "fall" greater in some districts than others. Planting and land-working generally is in abeyance, and the intense cold of the opening days of March will not be soon forgotten. In the neighbourhood of London there was a considerable fall of snow on Monday; this, however, rapidly thawed, and had disappeared on Tuesday, when it was followed by sharp frost and another slight fall of snow on Wednesday, accompanied by keen winds.

—"JUVENIS" sends the following note:—"I have read several very interesting articles lately on 'HYBRIDISING SWEET BRIAR' and 'H. P. ROSES,' and can quite understand that it would be difficult to make use of any late-flowering autumnal Roses. Surely there are some early summer Roses worth the experiment. Have any of your readers ever tried to hybridise Sweet Briar and York-and-Lancaster Rose, or Sweet Briar or *Rosa rugosa*, or even the *Polyantha* Roses, with the desire of procuring scented foliage?"

—THE OXFORD ROSE SOCIETY will hold its thirty-fifth annual exhibition in New College Gardens, Oxford, on Thursday, July 8th. The schedule of prizes includes eleven classes "open to all England," and ten others limited to "Amateur Members of the Society." The money prizes range from "£7, for 48 triplets," to "5s. for one bloom." Exhibitors coming by railway have their boxes met and conveyed to and from the Show free of charge.

—"A. M." asks "If correspondents will oblige by giving the best SELECTION AND SUCCESSION OF PEAS, extending over as lengthened a period as possible, and continuing in unbroken succession till late in the autumn. This information will be very thankfully received. Mr. Marriott's plan seems more for exhibition purposes than for the supply of a family."

—MESSRS. W. HEATT & SON write:—"As we have received numerous inquiries in regard to the extent of damage suffered by us in the FIRE IN COVENT GARDEN MARKET on Saturday last, February 27th, we should feel obliged if you would find space to intimate to our many friends that the damage sustained by us was very slight and does not in any way interfere with the conduct of our business, which is being carried on as heretofore." The damage at this fire was confined to the shops at the east end of the Central Avenue, but several of these were completely gutted, and the roof was damaged for a considerable distance.

—MR. BARDNEY informs us they have had SHARP FROSTS there during the past week varying from 4° to 10°. "March 1st was the most winterly day experienced this season. The wind has been piercingly cold and drifted the snow that fell during the night. Early in the day the wind changed and snow commenced falling heavily from the east, and continues without signs of abatement. We have now more snow lying upon the ground than we have had all the winter. This has been a long, dreary, sunless winter in this locality, and one of the worst that I remember for conducting forcing operations. We never have much sun here in the winter, but we have had less this than for some years past."

—"A. M. B." writes as follows on the WEATHER IN MID-LINCOLNSHIRE:—"February closed in sullen and severe frosts; March enters with the same bleak, bitter aspect, and since about 8.30 A.M. snow has been falling, fine but continuous. Everything looks once more white and winterly in thick snow. The scent of snow has not been out of the air for many weeks. Apparently shrubs, Rose, and fruit trees have not suffered much as yet."

—PRESENTATION TO MR. J. H. FORD.—On Thursday, February 26th, the Richmond Horticultural Society entertained their Honorary

Secretary, Mr. J. H. Ford, at a complimentary dinner in the Masonic Hall, when he was presented with a substantial testimonial in recognition of his services. This consisted of a handsome gold watch and a purse of 100 sovereigns, which had been subscribed by members of the Society and friends. The chair was taken by Sir J. Whittaker Ellis, Bart., and there was a large attendance of the leading horticulturists in the district. Several speeches were made, and Mr. Ford was highly complimented upon the satisfactory manner in which he has conducted the Society's affairs.

— THE NEW PARK AT EXETER.—We learn that Messrs. Lucombe, Pince & Co.'s tender for the supply of the ornamental trees and shrubs required for the Belmont Pleasure Grounds at Exeter has been accepted by the Exeter Town Council.

— "M. C. B." writes—"I have had some seeds from New Zealand of a plant called KOWHAI NGUTTI KALIA. Can any of your correspondents tell me what is the correct botanical name, and what is the proper treatment? They are being raised in a hotbed. How shall I treat them?"

— THE gardeners and labourers employed in the ROYAL HORTICULTURAL SOCIETY'S GARDENS at Chiswick and South Kensington were entertained at a supper provided for the occasion at the Bolton Hotel, Chiswick, on Friday evening, the 26th ult. The chair was taken by Dr. Robert Hogg, who was supported on the right by Mr. A. F. Barron, and on the left by Dr. M. T. Masters. The vice-chair was filled by Mr. J. Shirley Hibberd, supported by Mr. Thomson and Mr. Summers. About thirty sat down to an excellent repast, which being over, the remainder of the evening was spent in songs and speeches, all present giving evidence of the pleasure they seemed to derive from this gathering. The occasion was prompted by some members of the various Committees who are accustomed to meet during the year at Chiswick to conduct experiments of various kinds and to report thereon. These gentlemen having received much useful assistance from the young gardeners and others employed in the Garden, and who made in many cases personal sacrifices that these experiments should not fail through want of attention, considered it a proper recognition of their assistance to invite them all to a supper. We hope that this will be but the beginning of a long series of such entertainments.

— REFERRING to MILDEW ON ROSES "Borderer" writes:—"Though I have had by me all last year the 'Gardeners' Year Book, 1885," yet it was only the other day that I read in it Mr. Worthington Smith's most interesting article on 'Rose Mildew,' but in which he unfortunately has to say that he cannot point out how it can be prevented. I was, when reading the article, reminded that I saw in a number of the *Journal of Horticulture* last year a statement that dressing the soil of a Rose bed with gypsum was a great preservative against, if not preventive, of mildew. Can any of your correspondents kindly inform me if this is generally found to be successful, and in what quantity the gypsum should be used?"

— THE NARCISSUS COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY will hold three meetings during the coming season—viz., on March 23rd, April 13th, and April 27th. The proceedings at each of these three meetings will be conducted as follows:—The Committee will meet in or near the conservatory at 11 A.M., when a list of the specimens sent in for examination, and of questions for discussion, will be presented. The Committee will first determine what specimens and questions it will take into consideration, and adjourn in order that members of the Committee may examine the specimens. At 1.30 P.M. the Committee will re-assemble and proceed to the discussion of the specimens. It is hoped that those interested in the Narcissus will send up to one or other of these meetings any new or interesting forms they may possess. All such specimens should be sent in so as to arrive at South Kensington not later than the day before the meeting. They should be addressed to the Royal Horticultural Society Narcissus Committee, and each specimen should bear a label (waterproof) with the sender's name and some number by which it may be recognised, and be accompanied by a statement of the inquiry which the sender desires to put to the Committee, and of any facts which may guide the Committee in their decisions. The Committee will also be glad to receive communications or inquiries relating to the natural history and culture of Narcissus, also suggestions for investigation.

— A CORRESPONDENT remarks that—"Those who have not yet

obtained AZALEA DEUTSCHE PERLE should do so at once. It is without doubt the finest semi-double white variety that has yet been raised. The flowers are of large size, pure white, and their beautiful shape will commend them to all who have many bouquets to make. For early forcing A. narcissiflora is the variety relied upon, and we have a large stock of that, but its greatest defect is its poor badly coloured foliage. A. Deutsche Perle has fine dark green foliage, flowers very early, and when well known will certainly be the most popular white variety for early forcing."

— A GARDENER observes that "STATICE SUWOROWII is a charming plant when well grown in 5 and 6-inch pots for purposes of decoration during the summer months. At that period of the year it is totally distinct from other plants in flower, and is at once striking and effective in any arrangement of plants. Those who have effective and telling groups of plants to arrange either at home or in the exhibition tent should give this plant a trial, for in such arrangements its slender stem bearing its light pink flowers stand out boldly. It is easily grown. The seed should be sown in heat and the plants pricked off when large enough, and then potted into 3-inch pots, and from them into the sizes named. It will do well in any moderately rich fertile soil. Care must be taken not to grow the plants too warm. They must be gradually hardened to greenhouse treatment, and later in the season to the cool airy conditions of a cold frame. The treatment that will suit *Rhodanthes* after they are about 1 inch high will suit this plant well."

— WE have received from the NATIVE GUANO COMPANY, 29, New Bridge Street, Blackfriars, London, a pamphlet showing the results of the application of their manure in the field and the garden in the form of testimonials from cultivators who have applied it to various plants and crops. It may be remembered that Mr. H. S. Easty expressed his high approval of Native Guano on page 126 for Potatoes. The directors would invite the assistance and co-operation of landowners, farmers, and others to help in extending the use of the A B C process in their own neighbourhood, thus subserving not only their own direct interests, but also the welfare of the community at large. The multiplication of works for the treatment of sewage by this system would not only improve the sanitary condition of towns, but the manure being produced in proximity to farms, &c., would not have its costs augmented by carriage charges. Thus, what is now a nuisance to towns would become a source of profit to the country generally, and especially to farmers, who would have a valuable manure produced almost at their own doors. So far as we know, this is the best and cleanest method of disposing of the sewage of large towns.

— "J. R. S. C.," states respecting the CATERPILLARS complained of (p. 151) as destroying the blossoms of fruit trees (? *Carpocapse pomonæ*), "Perhaps the early application of some bitter substance, such as decoction of quassia, or something odorous, such as very weak solution of petroleum, syringed over the twigs, might prevent the moths from depositing eggs. The mite observed to infest *Eucharis* (p. 163) I am not sure about, but I presume it is a trombidium (allied to the harvest-bug therefore) and not one of the spinning mites of the genus *tetranychus*, so familiarly represented by the red spider of our houses and frames. Mites of the trombidium group pierce into plants, chiefly those of succulent and low growth. It has been urged that they do occasional benefit, because they have been taken preying upon parties of aphides."

— GARDENING APPOINTMENTS.—We learn that Mr. J. Udale, who has been for eleven years gardener to J. Watson, Esq., Shirecliffe Hall, Sheffield, and is well known in that district as an able horticulturist, has been appointed head gardener to Howard F. Paget, Esq., Elford Hall, Tanworth. The following have been made through Messrs. John Laing and Co.'s Nurseries, Forest Hill, London, S.E.:—Mr. Frankis as head gardener to Mrs. Grummont, Hatcham Grove House, Kent; Mr. A. Hawkes as gardener to Mrs. Williams, Palewell, Richmond; Mr. Hutton as gardener to E. de la Penha, Esq., Grove House, Clapham, Surrey; and Mr. Johnson as gardener to Arthur Bray, Esq., Bickley Park, Kent.

— AT the last weekly meeting of the members of the WAKEFIELD PAXTON SOCIETY an able and very comprehensive paper was read by Mr. J. H. Turner, the Hon. Treasurer of the Society, on "The Drainage of Land," a subject to which the Lecturer has for some years devoted considerable attention, inspecting from time to time the most important drainage schemes at home and on the Continent. Mr. Oxley presided, and Mr. Tunnacliffe occupied the vice-chair. After speaking of the useful

function which our rivers and streams perform as natural drainers of the land, Mr. Turner showed how important were the advantages which accrued when land was systematically and properly drained of superabundant moisture. By a thorough system of drainage the use of tillage was rendered much more effective, the land had an increased temperature in consequence of lessened evaporation, it was easier to cultivate and less labour was required in the operation, and, finally, the crops were earlier and more abundant. There was a long and interesting discussion, which was, however, entirely in harmony with Mr. Turner's paper. A hearty vote of thanks was given to Mr. Turner, on the motion of Messrs. Fallas, Newton, Tunnacliffe, and other gentlemen, who bore testimony to the valuable and practical character of the paper.

— IN the Transactions of the Penzance Natural History Society, Mr. Colenso calls attention to the rapidly increasing value as an article of export from New Zealand, of a NEW EDIBLE FUNGUS—*HIRNEOLA POLYTRICHA*. This Mushroom, first described from the East Indies and Java by Montagne, is of various sizes and shapes, some specimens measuring even a few inches. It is found in New Zealand growing on the trunks of trees, both on living and on decaying ones, especially on the latter while standing, particularly on the stems of *Corynocarpus laevigata* and on *Melicocyttus ramiflorus*. Both of these are endemic. The former is mostly confined to the seashore, where it often forms dense and continuous thickets. The latter tree is scattered plentifully throughout the country. When dry the Mushroom becomes shrivelled up, and is as hard as horn; when wet it is soft and elastic, almost sub-gelatinous. It grows in compact gregarious masses. The market for this fungus is China, where it is largely used by the Chinese in soups. It appears that another species of the same genus indigenous in North China has long been an article of commerce. Mr. Berkeley notes of our British species, *H. Auricula-Judæ* that it was once a popular remedy for sore throats, and adds that it is still occasionally sold at Covent Garden Market. The New Zealand species is plentiful, and obtained at little cost, the drying of it being an easy matter. Originally the price paid to collectors was 1d. per pound; now it is nominally 2½d., while its retail price in China is five times this. The declared value per ton at the Customs ranges from £33 to £53 a ton, and is doubtless much below its real value. During the last twelve years some 858 tons of this fungus were exported, chiefly from the ports of Auckland and Wellington, and of a declared value of almost £80,000.

### A COMPARISON OF MANURES FOR THE GARDEN AND ORCHARD.

[A paper by Professor G. C. Caldwell, Ithaca, New York, read before the Massachusetts Horticultural Society.]

(Continued from page 157.)

How do these prices compare with those actually paid for these plant nutrients in such animal or vegetable manures as gardeners or farmers buy?

Two or three years ago there came to me from a gentleman of this neighbourhood a series of questions as to the comparative cheapness of several of these manures. The questions could be answered, at least with a proximate satisfaction, since the inquirer was fortunately able to give me the cost per ton, at his own place, of all the materials in question. I had not time to analyse samples of the manures, and for the necessary information as to their composition I had to refer to the tables giving the average composition of such matters; if my estimates could have been based on actual analyses of the materials, they might have been somewhat, but certainly not very, different.

The results of my calculations are set forth in the following table:—

KIND OF MANURE	Cost per 1000 pounds.	1000 pounds contained of			Cost, in cents, per pound of the		
		Nitrogen.	Phosphoric acid.	Potash.	Nitrogen.	Phosphoric acid.	Potash.
	dol. c.						
Cow manure .. ..	1 16	4	1.6	3.6	19.2	10.8	6.0
Horse manure .. ..	1 54	7	1.5	9.5	14.1	7.9	4.4
Night-soil .. ..	0 43	7	14.0	2.0	2.8	1.6	0.9
Rockweed .. ..	1 21	4	2.3	4.0	20.5	11.5	6.3
Fish-chum, half dry ..	6 50	43	50.0	....	9.1	5.1	....
Hen manure .. ..	4 00	10	16.0	5.0	27.0	15.0	8.4
Tanners' waste .. ..	0 78	72	19.0	....	0.9	0.5	....

— If my figures are not wrong, the cow manure is not a cheap source of plant food; it would have to be looked upon as more costly than commercial fertilisers were it not for the large amount of humus-forming material that it contains; this may offset the high cost of the important plant nutrients in it. But then we have just as much of this humus-forming material in horse manure; and the important plant nutrients in that, instead of being

more costly than in the commercial fertiliser, are actually cheaper. The night-soil costs nothing except for the hauling; the plant food in it is remarkably cheap, costing only about a fifth as much as in horse manure; and one can see no reason why a pound of nitrogen in it should not be just as good for crop production as a pound of the same nutrient in horse manure. Rockweed is an expensive manure, much more so than commercial manures, while the plant food in it certainly cannot be any more available or valuable than in fine bone meal, or in good horse manure, or than in the fish-chum which provides nitrogen and phosphoric acid at half the cost.

Hen manure is another expensive fertiliser: its plant food costs more than that in any other fertiliser, natural or artificial. Even nitrogen in ammonia salts costs only 22 cents, and phosphoric acid in the best superphosphate only 10 cents a lb. From my point of view I should say that a great deal more was paid for that manure than it was worth. As to the tanners' waste I had to do some guessing; I took it to be mostly hair and clippings of fresh skins; it cost nothing, except for the hauling. If I was right in my conjecture as to its character, it is rich in both nitrogen and phosphoric acid, and is by far the cheapest manure of all; but its action may be much slower than many of the other manures in the list, which would detract from its value. Granting all that, it would still appear to be a very cheap manure.

Making all due allowance throughout these estimates for the possible deviations from the general average composition of such materials, I still affirm that where they come out so widely apart as they do in some cases, they indicate real and undoubted differences in the cost of the plant food that may be of considerable practical importance to the buyer of such manures.

We may look for a moment, before I close, at this same matter from another point of view. On the University farm at Cornell, Professor Roberts, by a careful system of saving and housing his stable manure, and rich feeding of his stock, largely milch cows, has obtained a product that, analysed in my laboratory, was found to contain 0.7 per cent. of nitrogen, 0.4 of phosphoric acid, and 0.84 of potash. The manure was applied at the rate of 10 tons to the acre, which quantity would contain about 150 pounds of nitrogen, 80 of phosphoric acid, and 160 of potash. These amounts of the three nutrients would cost, in a commercial fertiliser, at the same rates per pound as in the other calculations whose results have been given, about 40 dollars; but this 10 tons of manure did not begin to cost so much—it was the waste of the animals producing a revenue by their milk, or growth, or work. It did undoubtedly cost something, but I think it is safe to say not over 1 dollar 50 cents a ton, or half as much as the horse manure of which an account has been given above. This would make the plant food in it cost less than half as much as in that manure, and much less than in commercial fertilisers.

It may seem to many that thus far I have spoken only unfavourably of the use of commercial fertilisers; but I would not wish to leave you with the impression on your minds that I regard them with disfavour. On the contrary, I do not believe we could get along without them in general crop-growing; and I see no reason why, if they are judiciously used, they should not do as much for horticulture as they are doing for agriculture. If the farmer succeeds better in getting profitable returns from an investment in a certain quantity of nitrogen, phosphoric acid, and potash in a superphosphate than the horticulturist does, it may be because the latter has not learned by experience, as the former has, how to get such returns; and as long as he can procure animal manures by any sort of management, he will continue to use them rather than get out of the ruts and learn how to use something else in place of them. So far as the humus is concerned, on whose apparent usefulness I have dwelt so long, its due proportion in the soil can be maintained by green manuring, and without getting or making much stable manure, or by spreading over the uplands some of the contents of the muck deposits that are to be found on so many farms.

In order, however, to enable these commercial manures to compete with the cheaper plant food in animal manures, they must be bought at such rates, and in such ways, as to reduce the cost of the plant food they contain to as low a point as possible. A comparison of the cost of plant food in mixed fertilisers, such as superphosphate and special manures, with cash prices for precisely the same quality in the raw materials used by the manufacturers for making up these mixed fertilisers, shows that in the last two years consumers have paid from 18 to 20 per cent. more for the plant food in the former than in the latter, or the raw materials; or, stated in another way, about 33 dollars expended in the raw materials would buy just as much and just as valuable plant food as would cost 40 dollars in superphosphates or specials. These figures represent the average difference in favour of getting the raw materials directly; sometimes the superphosphate is sold at such low rates that its plant food is almost as cheap as in any other form in the market; but, on the other hand, the difference is sometimes very much larger in favour of the raw materials. For instance: in one case a Connecticut farmer was asked to pay, and perhaps he did pay, 45 dollars for a certain quantity and quality of plant food that would have cost him but about 26 dollars in the raw material. These raw materials are such as nitrate of soda, sulphate of ammonia, dried blood, and dried and ground fish-waste, any of which may be used for charging a fertiliser with nitrogen; plain superphosphate—that is, without any nitrogen—for supplying the soluble phosphoric acid, and potash salts for the potash.

A Connecticut farmer tried this home-mixing last year, using 4 tons of dissolved bones, 1 ton of muriate of potash, and 1 ton of sulphate of ammonia, making thus an excellent and really ammoniated superphosphate. It cost him, including materials, freight, and labour, 36 dollars 20 cents per ton; analysed at the Experiment Station, it was reported to be worth, at current prices, 45 dollars, which was a very much better showing than was made by any one of the 50 samples of superphosphate analysed at the same station during the year. The consumer had at the same time the great advantage of knowing just what the mixture was made of; that, for example, its nitrogen was in the form of sulphate of ammonia, the most costly and the most valuable form of nitrogenous plant food, and not of roasted and ground leather-waste, an utterly worthless form of nitrogenous plant food. Other farmers of that State have done likewise, and with good results also, both in the analysis and in the field.

Instead of closing with some flourish of a peroration, it will, I think be more in keeping with the character of my lecture if I should sum up

in a few words the main points which I have attempted to explain or illustrate:—

1. That if the elements needed for the food of the gardener's or horticulturist's crops cannot be obtained in sufficient quantity from stable manure or other animal waste, they can be procured in the trade in unlimited quantity, and in every degree of availability depending on different grades of solubility, and in the greatest variety of mixtures, so as to suit any whim or fancy of crop or crop-grower.
2. That profitable crop-growing can be carried on, for many years at least, with these commercial fertilisers alone.
3. That the most evident distinction between stable manure and commercial fertilisers, and the distinction upon which we should therefore naturally base an explanation of the greater reliability of the former, is its large proportion of vegetable matter, or humus-forming material, of which commercial fertilisers contain practically none.
4. That soils contain, in a difficultly soluble condition, and therefore not easily fed upon by the crops, large supplies of all the needed elements of plant food.
5. That humus, through its decay in the soil, furnishes carbonic acid, among other solvent agents; and this carbonic acid appears to play an important part in the nourishment of crops by bringing the native insoluble stock of plant food within their easy reach.
6. That even if we add water-soluble plant food to the soil it becomes largely insoluble before the crop can feed upon it, or needs it; therefore soluble plant food added to the soil in commercial fertilisers needs also the help of the humus, finally, for its solution.
7. That plant food in most animal and vegetable residues used as manures costs much less than in commercial manures.
8. That, in spite of the disadvantages which, under some conditions, attend the use of commercial fertilisers, they are nevertheless a very important and necessary help in crop-growing.
9. That in using these fertilisers the wisest course appears to be to make one's own mixtures of the raw materials, as well for securing a better manure as for economy in first cost.

### CANKER IN FRUIT TREES.

At the weekly meeting of the Astwood Amateur Gardeners' Society, on Monday last, Mr. J. Hiam resumed the discussion on this subject. The last reference in the Journal to canker was to the effect that it was doubtless owing to bad drainage and cold clay subsoil. This theory was completely rebutted by individual cases mentioned one after another by Mr. Hiam, and from a specimen tree brought to the meeting. It was pointed out, for instance, that some of the worst specimens of cankered trees in the neighbourhood stood in marl banks 20 or 30 feet above the road, on cuttings through embankments; one, for instance, could be seen on the top of Mussy Hill, where no bad drainage could have occurred since the flood; or on the borders of marl pits with many of the large roots actually out of the ground from the earth shivering down with the frost, while perfectly healthy trees were growing within a few yards. Also that perfectly healthy trees in his orchard, 4 feet 6 inches in circumference at the butt, had not had their roots disturbed since they were planted forty years ago, whose roots were doubtless in the "cold clay," or they would have been blown away, while other young and otherwise healthy trees whose roots were in good old loam were killed even before they began to bear. He pointed out further on in the same article referred to that softsoap was used to kill American blight, and of course it killed the other insects which have so repeatedly been referred to, which do not appear to have a name. They were again shown as specimens. The feeling of the meeting appeared to be unanimous that there was no doubt whatever that insects caused the wounds, and that insecticides were the prevention and the cure.—J. H.

### LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.—No. 7.

PASSING through St. James's Park, as I was "stepping westward," I noticed a little group engaged in the survey of an old Elm which had just been grubbed up. It appeared, however, that the persons were not lamenting its removal, but speculating as to its age and the quantity of wood it contained. I have repeatedly observed that, in regard to the age of trees, those who are ignorant of arboriculture are apt to make conjectures of the wildest sort. As wild are the exclamations some folks indulge in when from time to time decayed trunks are removed from the West End parks. Of course one regrets that they must go, but there are many about the parks that have already been too long reprieved, for they have hollowed branches actually dangerous during a gale. Doubtless all these might be lopped off, but where is the beauty of a mere trunk, and, should the tree be an Elm, that is liable to be suddenly uprooted? Our London Elms suffer much from the weakening attacks of the boring caterpillar of the goat moth, which might be even more troublesome were it not for the London sparrows. These dart down upon both male and female moths as they fly amongst the trees, and as each female contains about 800 eggs, every one that is killed settles a goodly number of embryo caterpillars.

So enclosed was it with walls and the rear premises of dwellings that few persons passing by had any knowledge of the extent of ground in Chelsea Park, or of the magnificent trees there; some few are spared, but the many have succumbed to the builder. Ten years ago one could there survey an avenue of Elms not, I think, to be rivalled anywhere about the neighbourhood of London, and many handsome Poplars. Of the rows of Mulberries planted in Chelsea for the purpose of silk production no trace remains. At one time Mulberries were numerous in London gardens, even near the heart of the City. But it does not seem to be a

tree planted now, though it will live on tolerably well amid smoke and fog, as witness sunbry aged specimens I have seen removed within the last twenty years, and yet a few exist, which may possibly be above 250 years old. Long was there cherished the Mulberry of the ancient Manor Garden at Chelsea, under which sat Queen Bess, so the tradition goes, to learn her tasks. Its place is lost, but we know the spot where her Elm once stood on the outskirts of the Park, which sheltered her under a sudden shower of summer.

Chelsea is not badly off for open spaces now, in or near it, though the Chelsea men let their Common go and the Park is laid waste, and Cremorne Gardens built over, also the ground attached to the old Pavilion, ground memorable because it had some of the picturesque work of Capability Brown.

Just on the edge of Chelsea—in fact, once reckoned as part thereof before the names of Pimlico or Belgravia appeared—was the farm of Aybury or Ebury, formerly with extensive market gardens, which diminished at last to the central space of Ebury Square; this, after struggling awhile as a nursery, was made into a recreation ground, much needed by the dwellers thereabout, but in truth it is not very attractive, perhaps for want of funds. The smallness of the space forbids the idea of much tree-planting, therefore it is desirable to make the enclosure bright with flowers as far as possible, or at least with cheerful-looking shrubs. Owing to the protection from rough winds that plants have in some suburban districts, it is easy to keep a few autumn species blooming until we are hailed by those that are spring pioneers. In such places as Ebury Square, Everlastings, particularly Helichrysums, would flourish and last on a good while, so would some Pansies and the familiar Convolvulus. The dwarf dark-leaved Beet would also be an attractive plant, standing moderate frosts. Lobelias of various kinds are getting to be freely introduced in these smaller spaces, and certainly with advantage. Another hint I gleaned from this square, which I throw out for the gardeners of similar spots, and that is when your grass does not incline to grow well the simpler the outlines of the flower beds surrounded by it the better. Prefer squares or circles to designs of varied lines or angles, which only make the poorness of the grass more obvious.

Those who may wish to see London evergreens to advantage may be advised some time in the dull season to visit the Royal Hospital Gardens, Chelsea. Not that this place offers any number of choice or unusual sorts. Wellingtonias, Deodars, and others no strangers to us, are conspicuous by their absence only, but the older favourites muster well, and the walks in that part of the gardens near the Bridge Road are agreeably sheltered by mounds and banks of evergreens, perhaps here and there too closely set; and it may be because some of these thrive where the less sombre species seem to flag, that there is an array of the dark Yews, Cypressess, Thujas, Firs, Junipers, Bays, and varieties of the Box. There are fine examples of the Japan and Cherry Laurel, of the Barberry and Sumach, intermingled with Hollies, many of which doubtless surpass their companions in age if not in size. As elsewhere, so much partiality has been shown to the Privet that it is used not only for hedgerows, but also placed in clumps; it seldom puts out any flowers when growing in London, even if not subjected to the frequent clipping sometimes inflicted upon it. The Laurustinus is another shrub that is generally prevented from blossoming by the town atmosphere. In what is called the Governor's Court the central space contains a group of large shrubs, almost trees some of them, that may have been planted at an early date of Her Majesty's reign, surrounding an antique summerhouse, and these evergreens show the advantage of the screen from the north-east wind which a pile of buildings gives on contrasting them with others on the bleak boundary of the gardens. Along the south terraces towards the Thames the beds contain a good show of flowers during the summer, but they look bare to a February visitor. Some of the old pensioners greatly interest themselves in the little plots of garden they are allowed to cultivate, and they manage to gain a trifle by selling to visitors pots of Musk, Pelargoniums, &c.

Quite recently the last of the Ranelaghs, a man better known to London volunteers than to gardeners, was laid to rest in Brompton Cemetery. Few strollers about the Hospital gardens call to mind his ancestor who died in 1733 possessor of a Chelsea estate, a nobleman, too, who had distinguished himself as a patron of horticulture, with a turn for experimenting. When the Government acquired the property a part of Viscount Ranelagh's grounds was added to the east side of the above gardens; part became streets and roads. The name of Wilderness Row was for awhile a reminiscence of a plot which, according to the Georgian fashion, was planted to exhibit a natural wildness. Nearly all the trees hereabout show signs of being younger than his lordship's time, the possible exceptions are some White Poplars and Elms. The soil here is well adapted for species of the Poplar family, also of course for Willows; and near the Thames bank were formerly many Willows, one walk specially a favourite, beside which ran a streamlet, fed by springs within these gardens, but this has dried up, and its shading Willows are gone. There yet remains, however, that somewhat peculiar double line of old Elms, the branches of which were tied back when the trees were young, so that they now present odd angles as they bend down from the trunks. Ash trees, so common in Pimlico Gardens, are scarce about Chelsea.

Fronting the Royal Hospital is a square space open to the public called Burton's Court. There are rows of Limes; the avenue down the middle has the finest and oldest trees. They were planted at a time when there was a scheme afloat for forming a grand avenue of these and other trees to extend from Chelsea to the Palace of Kensington. A number of the Limes in this space have the curious disfigurement I have elsewhere seen—viz., a seam or cleft reaching from the base of the tree almost to its top

I do not think this is caused by an insect. Here also some old Elms and Poplars, with juvenile Sycamores and scattered shrubs.—J. R. S. C.

### DEATH OF PROFESSOR MORREN.

THE announcement of the death of Professor Edouard Morren of Liège will be received by a wide circle with profound regret. At the comparatively early age of fifty-three he closed on the 28th ult. a life which was spent ungrudgingly in advancing the study of botany and horticulture; and he has left behind him a band of devoted friends, who will not cease to mourn his departure.

Dr. Edouard Morren was the son of Professor Charles Morren, a distinguished Belgian botanist, and whom he succeeded in the Botanical Chair in the University of Liège. He was born at Ghent on the 2nd December, 1833, his father being at the time Professor of Physics in that university. From the time of his appointment Dr. Morren devoted himself assiduously to the duties of his position; and though he has not left behind him any great work, his contributions to periodical publications have been both voluminous and valuable. In 1855 he undertook the editorship of *La Belgique Horticole*, which his father founded in 1850, and which has been continued up till the present time, though, in consequence of his failing health, its publication has of late been somewhat irregular. It is in the pages of *La Belgique Horticole* that his most distinguishing work has appeared, and this is a monograph of the Bromeliads.

The Botanical Institute of the Liège University and the Botanic Gardens of the same town owe their origin to the exertions of Professor E. Morren, and have become established amongst the leading institutions of their kind in Belgium, forming admirable monuments to his energy and botanical knowledge. The gardens are of moderate extent—about ten acres—and are situated in the town within a convenient distance of the station. They are tastefully laid out, and contain two extensive ranges of glass houses in the northern portion of the garden, one consisting of a series of divisions forming three sides of a quadrangle mostly occupied with small plants, and the other on a slightly elevated plateau is devoted to larger specimens, including some handsome Palms. The great feature is, however, the collection of Bromeliads, which is the most extensive in cultivation, several houses being appropriated to the larger genera. This family had been made a special study by Professor Morren, and the formation of such a wonderful collection has been the work of several years. Houses are also allotted to tropical aquatic plants—Cactaceæ, Orchids, Ferns, Nepenthes, and Marantas—Palms having considerable space in the large range mentioned. Not only are the collections interesting botanically, but they are remarkable for their excellent health, and such good culture is rarely seen in establishments of this kind, especially on the Continent. A portion of the garden is devoted to hardy plants, and a rockery has been recently formed for alpine. The trees are mostly of moderate size, but there is a good number of species, and it is evident in every department that the utmost has been made of the space at command. Professor Morren took a thorough interest in horticulture as well as in botany, and visitors from Great Britain were always sure of a kindly welcome.

### THE CLAPTON NURSERIES.

A VISIT to Messrs. H. Low & Co.'s nurseries at Clapton is almost bewildering to a stranger, and the enormous number of plants grown is surprising even to those who are familiar with the large trade collections. Orchids are a great specialty, and to them innumerable houses of all sizes are devoted; Palms and Ferns also occupy much space, Bouvardias and Tree Carnations constituting other important features, each having several large houses appropriated to them. A considerable number of Heaths is grown at Clapton, but not so many as used to be the case, for these with Cytisus, Camellias, and other plants have been transferred to the Enfield Nursery, where they are grown in thousands. A hurried run through the Orchid houses at Clapton gives some idea of the demand existing for such plants and how it is supplied. There are scores of houses, and all packed with rare, valuable, and useful Orchids. Numberless Cattleyas of the best species in all sizes up to enormous specimens 3 feet or more in diameter, with large leaves, leathery in texture and rich dark green in colour, the pseudo-bulbs stout and plump. Phalænopses are also wonderfully abundant, a grand stock of plants being comprised in three or four large houses, and all the plants are in capital condition, many flowering and others giving promise of a magnificent display later on if the weather prove favourable. Dendrobiums have much space devoted to them, and amongst the ordinary stock of species is a pretty display of an excellent winter-flowering Dendrobe, *D. luteolum* (fig. 29), which was introduced by this firm some years ago. This is a charming, easily grown Orchid for winter, and the flowers are of a most pleasing soft primrose tint. It flowers abundantly in an intermediate temperature, and the blooms last well either on the plant or cut and placed in water. Cypripediums of all kinds are admirably grown, and that handsome species, *C. Lawrenceanum*,

is represented by a stock of plants such as is seldom seen. A novelty with finely marbled foliage has also just flowered and been submitted to Professor Reichenbach for name; the foliage is very handsome, something after the style of *C. Hookeræ*, but the flower we did not see. Vandas, Aerides and all the other leading genera are also represented in these and other houses.

Odontoglossums are in strong force, seven or eight long houses being devoted to *O. Alexandræ* and its varieties alone, and they are all growing like young Lettuces. It is said that 150,000 of these Orchids are grown, and the number does not appear to be exaggerated when the stock is seen. Some grand varieties are flowering amongst them, and one richly spotted form opening on the day of our visit will probably take a place amongst the high-priced novelties of the season. Particularly important just now is a houseful of imported Orchids just received in excellent condition and comprising some of the best examples of *Vanda cœrulea* that we have seen. Huge pieces with fresh, healthy-looking leaves such as none would fear trying to establish are abundant, and it is seldom that this favourite Orchid is imported with such little injury. There are more failures in attempting to establish imported plants that have suffered severely in transit than from any other cause, and one of the surest means of succeeding with such plants is to obtain those in a plump condition. This is more especially necessary with the non-pseudo-bulbons Orchids which have no reserve supplies of nutriment to support them, and Vandas are most easily injured permanently. Throughout the nursery the health of the plants is astonishing, and it is evident that they receive excellent cultural attention, for such large collections would soon show the effects of carelessness in a most disastrous manner.

### CHAMÆROPS HUMILIS.

WE have a large plant of *Chamærops humilis*, which was raised from seed about fourteen years ago. It stands about 6 feet 6 inches high, including a No. 2 pot. For the last three years it has thrown out fruiting spikes, which grow out about 8 inches, and some of the little heps grow as large as a Sweet Pea seed, then fall, and the spike dies. The plant stands in theinery, having the same temperature as the Vines, and is so placed as to get the sun from ten o'clock all day. We keep it rather dry all winter, and never have any fire heat before the Vines are fairly started—say about the end of March or beginning of April—after which the sheath makes its appearance from the axils of the leaves; then we begin to give it some liquid manure made from soot and cow dung, at the same rate that we give to other plants, but more often. I have tried every means that I can think of, but cannot bring the fruit to perfection. I should feel very grateful if any of your correspondents could assist me in the matter.—H. H.

### HIMALAYAN RHODODENDRONS.

To see one or two of these after such a prolonged dearth of flowers indoors is indeed a pleasant sight, especially as the colours are so attractive. *R. arboreum* and *R. argenteum* are now in full flower, and they are very welcome in a large conservatory with many others, some of which are just bursting their buds. They are planted out in beds, the house being heated only to the extent of excluding frost. Planted in such cool structures seems to be the only way to get them to flower early. Those from both Nepal and the Himalayan Mountains mostly defy all attempts to bring them to a flowering state out of doors north of London. We have often heard of trials being made, but we have never yet heard of a real success. We have tried in the most sheltered places in our garden, under trees which gave a good protection, especially in spring, and also in warm greenhouses, with results which were far from being satisfactory. In such localities as the Isle of Wight, certain parts of Cornwall and Devonshire, fair success may be attained with most of the species. It does not appear that the plants are incapable of standing even our severe frosts when not in a growing state; but here is the difficulty. They seem to grow just at the time they are not wanted, and, like many other plants we try to grow in the open, they are severely cut or destroyed by late spring frost. A few days of mild weather in early spring bursts the buds or develops them to such an extent that they are easily damaged. The loss of their leader forces the shoots to break perhaps at three or four places; the result is weak shoots totally unfit to stand the late autumn frosts, and which, from the weakened state of the plants, rarely show flower until the second year if they have managed to escape the first.

Frigid domo, light mats, and other material are often used for protection; but as this entails considerable labour it is a very doubtful question whether it will be even half repaid by results; besides, the larger the plants grow the more labour is required in covering, and which extends over two or three months in the early part of the year. That they will not succeed in most parts of England without protec-

tion of some kind has been proved, and it seems a hopeless task trying them until we obtain a warmer climate, as some expect. Our best plan seems to be to persevere in their cultivation indoors, and we may yet be able to flower them in a small state and keep them within

leaves 12 to 15 inches long, deep green, and wrinkled on the upper surface and silvery underneath. The flowers are 4 or 5 inches long and as many broad at the mouth, white tinged with rose, becoming deep towards the base, and together forming a glorious mass. R.

Fig. 29.—DENDROBIUM LUTEOLUM.

the desired limits. Planted out, however, where they can have plenty of head room they form enormous bushes, giving an annual display of flowers, ranging in colour from the most intense scarlet to pure white, many of them also emitting a most delicious fragrance. *R. argenteum* is said to grow as a tree 40 feet high, with magnificent

arboreum has a much more compact habit, studded with bunches of intense scarlet flowers. Others, such as *R. Nuttalli barbatum*, *R. Edgeworthi*, *R. Falconeri*, *R. Aucklandi*, and *R. Thompsoni*, will soon follow, when we propose drawing attention to their merits in the order they appear.—M. S.

## HINTS ON ORCHID CULTURE.

As the following hints on the requirements of Orchids are chiefly intended for amateurs or beginners, the instructions have been made as brief and simple as possible, the object being to convey such information as will enable inexperienced persons to overcome the few difficulties most frequently encountered, and to guide them in the selection of easily grown species. The rapidly increasing popularity of Orchids has been materially assisted by the simplification of their culture, for so long as it was supposed that they could only be grown in highly heated houses specially constructed for them they were confined to few establishments. When, however, it was found what a large number could be successfully grown in lower temperatures in ordinary houses, the number of their patrons was speedily augmented. The increased demand caused larger numbers to be imported, and the result was a considerable reduction in the prices, which has placed them within the means of thousands who a few years ago would have regarded them as quite beyond their reach. It has been proved that a great part of the difficulty in Orchid culture was imaginary, and that with ordinary care the majority of Orchids can be grown satisfactorily. Some, of course, cannot be managed so readily, but these need not be included in small collections, as there are plenty of others to select from without them. Still, it is necessary to observe closely the peculiarities of the plants, and by arranging them in suitable positions in a house numbers of very different habit may often be accommodated as well as if several structures were at command. Plants frequently evince partialities for particular positions, and while thriving in one part may refuse to make progress in another a yard or two away. Such facts as these can only be learnt by observation, and success is largely dependant upon them. It is also highly important that the plants be always clean, or the best culture will be nullified, and one of the most experienced orchidists of the present time attributes the health of his plants mainly to keeping them free from insects. With close attention to these, and similar apparently small matters to be afterwards referred to, no one need fear undertaking the cultivation of the most useful Orchids.

## PROCURING ORCHIDS.

**ESTABLISHED PLANTS.**—If it is intended to commence with a collection of established Orchids it is advisable to purchase small plants from any nurseryman who makes them a specialty. This is advantageous in several ways. Strong plants can be obtained that will not be so likely to disappoint the amateur cultivator. Any varieties or species required can be insured being true to name, and the plants having been properly potted will give little trouble the first year. They can also be purchased at prices to suit all pockets now, and the expenditure of from £5 to £10 will procure a varied little collection to start with, the larger amounts being chiefly required for the varieties or specimens of greater size. In the former case it is preferable to state what is required and the amount intended to be spent, leaving the selection to the nurseryman unless the buyer has a special liking for certain species. When a large collection is being formed for several houses it will have to be decided whether it shall contain as great a number of species and varieties as possible, or whether there shall be a quantity of some of the leading useful Orchids, such as *Odontoglossum crispum* (*O. Alexandræ*). In all cases it is preferable to form collections gradually, commencing with a small number and increasing them as the cultivator's knowledge advances.

**IMPORTED PLANTS.**—Some amateurs prefer starting with a number of imported Orchids, and though it is longer before the flowers are obtained, with some probable losses in the meantime, yet there is the chance of obtaining novel varieties amongst others of indifferent merit, and this alone induces people to purchase them. Imported Orchids may at times be procured very cheaply, and one amateur states that he never gives more than a shilling each for *Odontoglossums* and four or five shillings for *Cattleyas*, *Lælias*, &c., with others in like proportion. This, however, necessitates a frequent attendance at the sales, with a thorough knowledge of the plants. Importations vary considerably apart from the value of the species or varieties, for the condition in which the plants are received makes a surprising difference in their subsequent progress. Plants with comparatively fresh green leaves and stout pseudo-bulbs are worth very much more than those that have lost the greater part of their foliage, have withered exhausted pseudo-bulbs, and perhaps arrived at a time of year when they are likely to suffer from frost. These points have to be considered in purchasing imported Orchids, and there is so much uncertainty about it that it is far better to rely upon established plants for commencing and add to the collection afterwards as desired.

When, however, imported Orchids are obtained they require some care to get them into condition for potting or basketing. They must first be well washed in tepid water, and then be placed in a shady position in a temperature from 50° to 60°, the *Odontoglossums* of the

*O. crispum* character requiring the coolest place, and the *Cattleyas* and *Dendrobiums* the warmest. Those who import Orchids in large quantities usually devote a house to them, where they are either spread out upon a slightly moist stage or hung from the roof, the air being kept in a moist condition. The object is to induce the growths to "plump up," as it is termed; and when this has been effected and the roots are showing freely they can be potted in the usual way. When small numbers are being established the best way is to place the plants in pots of rough clean potsherds and charcoal. The neck of the plant must be well elevated, and some prefer laying the plants upon the surface until roots are formed. Mr. J. Douglas has in this way succeeded admirably with some Orchids ordinarily considered difficult to establish. Most of the non-pseudo-bulbous Orchids like the *Cypripediums* may be potted as described, and all seem better than when laid upon stages, as water can be supplied more freely. The principal point is to give sufficient moisture to induce root-growth without causing any portion of the plant to decay, as it is very liable to do after its long journey and the severe drying it has had.

## STRUCTURES FOR ORCHIDS.

The fanciful idea that peculiarly constructed and expensive houses of various kinds were essential for Orchids having been dispelled, it was soon found that much less depended upon the form of the structure than had been long imagined, and that if the requisite heat could be provided the plants would succeed in houses of all kinds and in all positions. The primary consideration is insuring the full exposure of the plants to light with sufficient means at command to break the force of the sun in the hottest weather. In our climate this is most important, for it must be remembered that exotic Orchids, even those needing the coolest treatment, come principally from equatorial regions, where, though at great elevations, they are exposed to a nearly vertical sun during a great portion of the year. The influence of light upon Orchids is astonishing; it matures the foliage and growths or pseudo-bulbs and lays the foundation for successful flowering another season, for with these, as most other plants, much depends upon the ripening of the current year's growth. It is advisable to employ houses with roofs that offer the least obstruction to light, those having large heavy rafters or broad laps being avoided; and it is absolutely necessary that the glass be kept clean at all times. Some advocate close glazing, relying upon the use of the ventilators for admitting the requisite amount of air, but in the cool houses for *Odontoglossums* and *Masdevallias* a kind of permanent ventilation is provided by leaving a space between the bottom pane of glass and the eave of about one-eighth of an inch, the glass overlapping the wood sufficiently to throw off the water; and in very severe weather these spaces can be stopped by pieces of wood. There is a large cool house at Downside, Leatherhead, with a roof constructed in this way, and it is rarely found necessary to use the plugs mentioned. For tropical Orchids of the *Cattleya* and *Phalænopsis* type the ordinary close glazing is preferable, and the ventilation can be satisfactorily arranged in other ways, as will be described under that head. It is important to avoid drips, as these are often destructive to Orchids, and the strongest plants soon suffer if exposed to them. Rafters are grooved the whole length to take off the condensed moisture that accumulates along the bars, but the most effective method is to have a narrow piece of zinc screwed or nailed to the under side of the rafters, and bent so as to form a little channel that will readily convey the condensed moisture to the lowest part of the roof.

The houses may be span-roofed or lean-to, according to convenience, and the aspect is not of very much importance, though the former may preferably run north and south for tropical Orchids, thus giving an east and west aspect for the two slopes, lean-tos for a similar purpose running east and west, with the slope to the south, or for cool Orchids to the north. A north aspect is not essential for cool Orchids. East or west, or indeed any aspect except direct south, can be made to suit them; but the more exposed these plants are to the rays of the sun in summer the greater the attention they will need in supplying them with water, and it is also frequently difficult to prevent the temperature rising unduly high; otherwise they must have the lightest position possible, and dark corners, or those much shaded by trees, should be avoided. Houses of moderate breadth and height are the best for most Orchids, but *Cattleyas* and *Lælias* thrive in lofty spacious structures better than other plants, and seem to prefer such houses, as can be seen in the cases of the two magnificent *Cattleya* houses at Mr. W. Lee's and Messrs. J. Veitch & Sons', the latter being probably the largest house devoted to Orchids in this country. It is 132 feet long, 22 feet wide, and 11½ feet high in the centre; and the plants are all in capital condition. In private collections, however, some of the best grown plants are seen in small houses, and for cool Orchids they are now generally employed with the roofs pitching on to the eaves nearly level with the side stage, thus dispensing with side-lights. For small-growing *Odontoglossums* and *Masde-*

vallias these are very suitable, but for taller plants and in warmer houses side lights are advisable, as they give greater space for arranging them and admit more light. A span-roofed house intended for a large miscellaneous collection of Orchids should be in two or more divisions according to its size, and the kinds of plants that are to be cultivated having the warmest division at the boiler end, and the coolest can be employed for *Odontoglossums* or plants in lower, as the blooms last much longer in a lower temperature and less moisture. A well built lean-to frame against the side of such a house can be used for *Odontoglossums* if sufficient piping be supplied to prevent the temperature falling below 40° in the winter, and in several gardens they are so grown with excellent results, the plants being placed upon a bed of sifted ashes and carefully looked after to prevent the depredations of slugs.

When houses are set apart for Orchids the staging to be employed requires some consideration. The plants need a constant moisture round the roots and foliage when in growth, and cool-house Orchids must have it at all times. This is provided in various ways. In some cases the stage is constructed of slate slabs with iron supports, and upon it is placed a layer of fine pebbles, spar, shells, small coke, or coal, the chief objection to the two last being their dull appearance, though they are now much employed in nurseries. Whatever material is selected it must be kept constantly moist by syringing or otherwise, and the plants are either stood direct upon the material or elevated on inverted pots. In Messrs. J. Laing & Co.'s nursery corrugated zinc is now generally employed as staging for Orchids and other plants, being covered with a layer like that described. It

Fig. 30.—An Orchid Case.

is very durable, and forms a useful storehouse of moisture, while preventing any undue accumulation: Open wooden stages are frequently placed over the solid stages and the plants arranged on these, where, if the supports are isolated by means of little cups kept filled with water, as is now practised in some of the best collections, there is no danger from slugs, woodlice, or other pests of that character unless they are introduced in the soil with the plants. In warm houses the lower stages are often planted with *Panicum*, small Ferns, *Selaginellas*, &c., which have a pleasing appearance and serve moreover to preserve a healthily moist atmosphere. They are sometimes objected to as harbouring insects, but with the double stage there is nothing to be feared in that respect. For

such houses as that at Oldfield, Bickley, where the *Phalænopses* are early all suspended from the roof, it is a great improvement and very beneficial. When central stages are employed they are usually of open lattice shelves, over tanks or beds of some material, old leaves being occasionally used as the moisture-holding substance. In many houses, especially those for *Odontoglossums*, tanks are constructed on each side of the path under the stages to serve as reservoirs of rain water, and to provide a continual supply of moisture in the air. If intended merely for the latter purpose they are usually only shallow troughs, 4 to 6 inches deep. Paths can be formed as desired, those of red or ornamental tiles having the best appearance, but those of any loose material, or even of the earth itself, are equally good as regards the health of the plants.

From the foregoing remarks it will be seen that houses can be easily altered and fitted to suit Orchids; but in some gardens it may not be convenient to go to that length, and the houses must be utilised as they are. This need not deter anyone from commencing the culture of Orchids, for some of the best can be grown with other plants. For instance, the ordinary stove will accommodate a far greater number of tropical Orchids than is usually supposed. Vineries or Peach houses where forcing is proceeding exactly suit numbers, such as *Dendrobium nobile*; and a warm conservatory, which in some places is maintained at a temperature intermediate between that of a stove and a greenhouse, is admirably adapted for many Orchids when in flower; and we have seen some extremely pretty effects produced by the tasteful grouping of *Dendrobiums*, *Oncidiums*, *Odontoglossums*, *Cypripediums*, and even *Phalænopses*, with Ferns and graceful foliage plants. At Furzedown, Tooting, the residence of C. Seeley, Esq., the gardener, Mr. Laing, has for many years made groups of this character a special feature in the conservatory early in the season. Cucumber and Melon houses, Pine pits,

forcing houses, propagating houses, warm frames, and other structures afford abundant space and convenience for the majority of heat-loving Orchids, the only house really unsuited for such plants being the greenhouse, in which the atmosphere is too dry and the plants too much exposed to draughts to thrive.

An instance was given some time ago in the *Journal of Horticulture*, showing how an amateur had succeeded in growing Orchids in a small case erected on a lead outside a window, which is worth notice as illustrating how easily Orchids can be accommodated. A diagram of this is given in fig. 30 which will be understood from the following explanation: *a*, the case 6 feet long by 3 feet wide; *b*, the window of the sitting room; *c*, glass door with 6 inches between it and the window, in order to prevent damp entering the room; *d, d*, ventilators; *e*, body of the case 6 inches deep, filled with sand, the bottom being well drained; *f, f*, hot-water pipes. The ventilators were wooden shutters 18 inches long and 6 inches wide, the space opposite these inside being covered with a woollen net on a frame to filter the air as it passed through. In this miniature structure with liberal supplies of water the owner succeeded in growing the following Orchids in a smoky district of London. *Aerides crispum*, *A. virens*, *Aganisia pulchella*, *Brassavola acaulis*, *Broughtonia sanguinea*, *Calanthe vestita*, *Camarotis purpurea*, *Coelogyne cristata*; *Dendrobiums formosum*, *Lowi*, *pulchellum*, *Jenkinsi*; *Huntleya marginata*, *Laeliopsis domingensis*, *Peristeria elata*, *Phalænopsis amabilis* and *P. grandiflora*, *Saccolabium curvifolium* and *miniatum*, *Sobralia macrantha*, *Sophranitis grandiflora*, *Stanhopeas aurea*, *insignis* and *tigrina*, and *Vanda suavis*.—AN AMATEUR.

(To be continued.)

## SOME SINGLE ROSES AS DECORATIVE PLANTS.

[An article by Mr. T. W. Girdlestone in the "Rosarian's Year Book."]

(Continued from page 158.)

MR. BAKER'S group VI., bringing together *spinosissima* and *Alpina* (the thornless Rose), is rather a satire on the classification of plants merely by general external appearances. I must own to a decided preference for the Touch-me-not Rose all set with little wilful thorns over the plausible insinuating *alpina* (or *pyrenaica*). A good plant of the burnet Rose in full bloom is a "charming sight to see," but though when cut fresh and young a bunch of Alpine Roses is pretty and very fragrant, the flowering is too desultory to be ever very effective on the tree, while nothing short of an earthquake, or at least a general upheaval of rocks, will secure the eviction of its suckers from any Alpine garden in which *Rosa alpina* may have been domiciled.

*R. Ecæ*, with its brown stems covered with equal prickles, appears a very characteristic plant, but I have not yet seen it flower; and a definite position is hardly yet assigned either to it or *R. Beggeriana nigrescens*, a slender growing but vigorous plant, producing freely numerous delicate white blossoms, which are very effective among the graceful bluish-green foliage, and which are followed by brilliant little heps like waxwork.

*Rosa canina* (IX.) may truly be called the slave of the Rose family, and like *Cinderella*, is only thought of in work-a-day garb, and is unquestionably sat upon. It is designated by the contemptuous name of dog, and then dragged out from the hedgerows to be the standard-bearer of Queen Rosa's army; it is cut to pieces to support the mounted infantry that they may achieve glorious victories, and be decorated with medals on the tented field; uniform drills are the rule for its very seedlings till they are drafted into the line for active service with the colours; moreover, it undoubtedly helped to originate many garden varieties, while some of its own variations are very pretty; and yet hardly anyone seems to think it deserving of a place even in the wildest of wild gardens. The versatile Gerard, in his quaint and gossiping *Herbal*, can hardly condescend so much as to mention poor *R. canina*, "a plant so common and well-known, that it were to small purpose to use many words in the description thereof; for even children with great delight eat the berries thereof when they be ripe, make chains and other prettie gewgawes of the fruit; cookes and gentlewomen make tarts and such-like dishes for pleasure thereof, and therefore this shall suffice for the description." (They must have had good digestions in those days, when it was possible to sharpen an appetite by botanising on the site of the present barracks, and gathering *R. pimpinellifolia* "in a pasture as you goe from a village hard by London, called Knightsbridge unto Fulham, a village thereby;" for the old Surgeon repeats that "the fruit when it is ripe maketh most pleasant meats and banqueting dishes, as tarts and such-like; the making whereof I commit to the cunning cooke, and teeth to eat them in the rich man's mouth!") Another aggravation to which *R. canina* is subjected is the treatment of its different forms. This Rose has gone into variations literally by the hundred, to try and obtain horticultural recognition, but without success. For as soon as it has elaborated a fresh attraction and appears in the glory of deeper colour, larger flowers, downy leaves, or what not, someone is sure to be ready with a sesquipedalian name of probably as many consecutive consonants as his own patronymic, and we are indulged with the "discovery of a new species!" The poor dog can gain neither credit nor admission any way. Some years ago, when a crowded train reached Cologne, certain English passengers, engrained with the black dust of the hot night journey, immediately started off to get a bathe, their German fellow-travellers, whose demands on the water supply were—well, more Teutonic—promising to keep their seats for them in the compartment. But when the bathers returned several shades lighter in colour, and radiant in clean collars, the exact mind of the Teuton refused to admit their identity with the whilom grimy companions, and informed them that they must find room elsewhere, that compartment being reserved! So that their smartened exterior nearly cost the renovated Englishmen their seats in the train. This trying to make a specific distinction between a

man before and after his bath is the sort of treatment that is discouraging to all effort in the direction of improved appearance—even when applied to Roses.

*R. rubrifolia* (IX.), of which Andrew's name of *lurida* is much more descriptive, is a very distinct and interesting plant, with its metallic-blue tinted foliage and weird quaint-looking flowers whose long attenuated sepals extend far beyond the rosy petals, a veritable Rose of Fairyland. The red-brown stems are covered with a bloom like that on black Grapes, and this blue colour seems to pervade the whole plant, making with the delicately tinted flowers a most perfect "arrangement" in rose colour and French grey. The beauty of the plant is maintained until late autumn by the great clusters of from fifteen to thirty smooth bright-red somewhat globular hips which succeed the bunches of flowers. Some of the varieties of *R. indica* (IX.) also are interesting from the freedom with which they bloom again during the autumn till cut off by frost, and for their intense fragrance.

*R. rubiginosa* (X.) (= *eglanteria*, *suaveolens*) our native Eglantine, or Sweetbriar, is much prized for its fragrant foliage, though it is only when they see the plant laden with hips that it seems to occur to some people that it must at one time or other have borne a very ornamental mass of flowers; and floral commendation is generally reserved for such varieties as the double scarlet Sweetbriar, a very pretty sort truly, but with neither the vigour nor the fragrance of the species. Nevertheless, one garden single variety is really a lovely Rose, with thick, pure white petals, each margined with a bright picotee edge of clear purple. It is very vigorous, and rejoices in the picturesque name of "Hebe's Lip," though why so is not obvious: since Hebe's lips could hardly have been so white as the petals, or so dark as the edging—unless she "enjoyed extremely bad health" as they say in the west, or else was perpetually sipping the ruby nectar she should have been handing round.

The white-flowered form of *R. pulverulenta* (= *glutinosa*), another member of this group, makes a pretty pendent on the rockery to *R. lucida*. It has compact white flowers which are succeeded by elongated red hips, and its smooth dark stems are clothed with deep green leaves consisting of seven rounded leaflets.

But, of course, it is by the so-called Austrian Briars that the rubiginosæ have been made famous in gardens. The double forms, Persian yellow, introduced from Persia in 1837 by Sir H. Willock, *lutea flore pleno* or Williams' double yellow, and *Harrisonii* sent from America in 1830, though somewhat similar, are all good and desirable Roses; but none of them exceed in purity of colour or grace of outline the single flower of the species *R. lutea*, a plant whose deep pure yellow blossoms, mounted on their brown stems against their natural background of dark-green foliage, produce an effect only eclipsed by those of its brilliant variety *R. punicea*. "Copper" Austrian Briar is a misnomer; for the petals of this Rose, though buff-coloured on the outer side, are of a dazzling orange-scarlet colour on the inside, which is fully displayed by the expanded flowers; and a few branches of this Rose and *R. lutea* lightly arranged in a good-sized piece of *Valerie* or other deep-coloured pottery, makes as distinguished a bouquet as can well be.

Let it not, therefore, be said that single Roses are not worth growing as decorative garden plants; for if their individual flowers are evanescent, they are also innumerable, and so the plants remain gay longer than many other Roses, even without reckoning their harvest decoration of scarlet fruit in the autumn; and the majority of them are no trouble whatever to grow. *R. berberidifolia* *Hardii*, *lucida*, and *nitida*, with *Ece*, *pulverulenta flore albo*, and *Beggeriana nigrescens*, are charming representatives of the genus *Rosa* for the rockery, and *R. polyantha* is the most rapid and ornamental of climbers; while, with all deference to Mr. George Paul, the true scarlet Rose (to speak pinaforically),

"Resisting all ambition  
To come fit for exhibition,  
Still remains a single Rose."

## ORNAMENTAL GRASSES AND EVERLASTING FLOWERS

Now that many amateurs and others will be scanning seed lists with the object of selecting plants which are easily cultivated and extremely useful, I would call special attention to the ornamental Grasses and Everlasting Flowers. These are not only pretty when growing in summer and autumn, but their heads and blossoms, when cut at the right time, remain in perfection throughout the whole winter, and this is a much-desired quality not found in most flowers. Tables may be decorated, rooms adorned, and all floral embellishments executed by their aid in the dead of winter. It would be impossible to imagine anything more pretty and graceful than many of the ornamental Grasses. They are exquisite, and add artistic finish to arrangements composed of the choicest flowers. Some seasons we have gathered many natural Grasses in the fields and moors, and when dried they were very useful for mixing with cut flowers generally in winter; but graceful as many of the wild Grasses undoubtedly are, many of the ornamental ones which are offered by seedsmen surpass them. They are sometimes sold in "collections," but varieties of no particularly ornamental character are apt to slip into these, and to make sure of growing none but the best each sort should be ordered separately. The following are the choicest varieties:—*Agrostis nebulosa*, *Anthoxanthum gracile*, *Briza gracilis*, *Chloris radiata*, *Cuix lachryma*, *Eragrostis elegans*, *Eulalia japonica zebrina*, *Hordeum jubatum*, *Panicum capillare*, *P. virgatum*, *Paspalum elegans*, *Stipa pennata*, *Tricuspis acuminata*, and *Uniola latifolia*.

The whole of these may be raised from seed, and they will all produce their ornamental heads before the autumn. In cold districts it would pay to sow a few 4-inch or 5-inch pots of each early in March, rear them in a cold frame and plant out early in May, but as a rule they can be cultivated to perfection without this labour. If the seed is sown in the open ground early in April the plants will soon appear and grow freely. Some make a practice of sowing them in patches in mixed flower borders, and very effective they are in

such positions; but when they are cultivated mainly with the object of securing the heads for winter decoration they need not be confined to flower beds or borders, but each may be sown in rows in any corner in the kitchen garden. I have generally found them do better when treated in this way than the mixed style, as in the latter case they are always liable to be overshadowed by other plants which may be taller.

They develop best in good soil, and to insure their colouring well in the autumn they should be sown where they are exposed to the sun. It is not necessary to sow the seed thick, and if covered about half an inch they will always thrive well. It is advantageous to get them to start freely, and to assist in this we generally cover the seeds with old sandy and rich soil from the potting shed.

Respecting the Everlasting Flowers, they are very suitable for associating with the Grasses, and as with these we prefer growing them by themselves when the object is to get a special lot of fine flowers for winter use. This, however, is not a hard-and-fast rule in their culture, and large quantities of excellent flowers may be grown in the mixed border by sowing a small patch of seed here and there. They may be sown at the same time as the Grasses, and will succeed under the same treatment in every respect. The early raising of plants in pots will also be found to be a remunerative practice in cold backward localities, as although the plants undoubtedly will grow freely enough in summer, the advantage gained by sowing early or under glass is that the flowers will form during the best of the summer weather, and can be harvested before any bad weather in autumn disfigures them.

*Rhodanthe Manglesi alba nana* is a new Everlasting, recently introduced by Messrs. Carter, of great beauty and usefulness. This variety is very dwarf, blooms profusely, and is of a charming silvery white colour. *Acroclinium roseum* and *A. album* should be in all groups of Everlastings. Other fine varieties are *Ammobium alatum*, *Morna elegans*, *Palafoxia Hookeriana*, *Waitzias* in variety, and *Helichrysums* of many colours. The latter are very hardy, strong-growing, free-flowering, and the blossoms are rose, scarlet, crimson, yellow, purple, white, and other shades.—J. M.

## NOTES FROM WORTLEY.

THE gardens at Wortley Hall, near Sheffield, are known by repute throughout the kingdom, and gardeners always expect to hear of something either good, novel, or surprising therefrom.

Mr. Simpson, for many years head gardener (and now gardener and forester), is so well known as a practical horticulturist that a visit to the gardens under his charge must necessarily result in benefit to the visitor. As the ground out of doors at the time these notes were made was covered with ice and snow, our attention is confined exclusively to the numerous glass structures. The first structure we entered was the late vinery, in which are hanging numerous bunches of average sized, well ripened bunches of the usual varieties of late black Grapes, but the object of special interest here is the Gros Guillaume Vine, which was prominently before the public some years ago as the pioneer of a new system in Grape culture. As the matter was well discussed at the time, I shall only say that the Vine is now in capital condition and promises to bear a heavy crop of fruit next season, and the stem now is 50 feet long, 20 feet having been cut off in order to make room for other varieties. In a greenhouse is a fine plant of *Acacia Riceana* trained under one of the rafters, and shortly its gracefully pendant shoots will be covered with flowers. This is a plant that ought to be more generally grown. Two plants of *Gloire de Dijon* and *Chestnut Hybrid* Roses will soon be covered with hundreds of sweet flowers. In an adjoining house is a good collection of *Vandas*, *Cattleyas*, *Lælias*, and *Dendrobiums*; the *Vandas* were specially robust, and amongst the *Dendrobiums* were *D. chrysotoxum* and *D. Wardianum* that had been subjected to the pruning system, and neither showed signs of deterioration, but appeared to be equally as robust as those that are not subjected to such treatment. The next house is a vinery planted with young Vines, and these, instead of being planted at the front of the house in the orthodox way, are planted along the middle of the inside border at distances of about 18 inches apart, and Mr. Simpson intends to train every alternate cane down towards the front of the house, thus obtaining the greatest amount of fruiting space possible, and at the same time allowing ample room for the free development of laterals and foliage. These Vines were planted from eyes last July, and duly reached the top of the house. They will be pruned back only as far as the perfectly ripened wood, and will be allowed to carry several bunches each. In strength they are not sensational, but are of short-jointed and medium-sized solid wood. As a crop of fruit was taken out of this house early last summer it will at once be seen that the vinery has been rejuvenated with fruitful Vines without the loss of a single season. The next vinery is about to undergo the same operation, but at present it contains some fine three-year-old Vines in pots. These were fruited last year, and Mr. Simpson says produced very good crops. They have evidently been well cared for, and will undoubtedly produce, during the present season, a satisfactory crop of good serviceable fruit.

Entering a span-roofed range in three divisions we observed a quantity of *Nicotiana affinis* in flower, the white sweet-scented blossoms being very abundant, and coming in at this season of the year they are doubly valuable. In the warmer division a good effect is produced by the tasteful arrangement of *Crotons*, *Thyracanthus rutilans*, and *Begonias*, all healthy and grown specially for house decoration. Particularly noticeable in the same house was a plant of *Allamanda Schottii* trained in parallel lines horizontally and laterally, a wonderful example of the rapid growth of this gorgeous trailer; and *Ipomœa Horsfalliæ*, trained from one end of

the house to the other in horizontal and vertical lines under the ridge of the house, was a specimen of successful culture rarely seen; it was planted last July. This plant is very liable to the attacks of red spider, and consequently it is seldom seen in good condition, because, as it is invariably grown against the glass and over other plants, it is liable to be neglected, and thus the red spider very often gets a good foothold before it is observed. It is a pity the flowers of the *Ipomoea* are so very short-lived, as the form of its flowers, with their delicate texture and soft rosy magenta tint, render it one of the most desirable of our stove climbers. A good specimen of *Diosma fragrans* was in flower in one corner of the house devoted to greenhouse plants. This is an old-fashioned plant, too much neglected at the present day, along with others of the same natural order. Why are not the *Correas*, *Croweas*, *Eriostemons*, *Boronias*, and *Choisya ternata* seen more frequently in our conservatories and greenhouses? I fear gardeners are not entirely free from the charge of neglecting these plants.

In pits heated by hot-water pipes plants for bedding out are grown in thousands. *Pelargoniums* are potted out of the beds and kept through the winter, cuttings being taken from them in spring. No doubt this is a good system to follow in high and cold situations, as it is generally late in the season before the beds are so dense with growth as to admit of many cuttings being taken without the beauty of the beds being destroyed for the season—at least, such is my experience, and there is invariably a large per-centage of failures amongst cuttings taken so late. The *Pelargoniums* at Wortley are now most luxuriant and ready to furnish a superabundance of good cuttings.

Amongst the Figs in pots was a variety Mr. Simpson speaks highly of. It appears he was much struck with the heaps of large luscious fruit of a particular variety which he saw in Paris in 1878. This variety, he says, is twice the size of Brown Turkey and equally as prolific, and certainly that is saying a great deal for it. If I caught the name correctly it is called "*Daphne d'Argenteuil*."

The trees in the early Peach house were in full flower and presented a beautiful sight. Two trees occupy the whole front of the house. These were originally "riders" on stems about 5 feet high, but they have been turned into "dwarfs" by replanting them with their stems forming an angle of 15° or 20° with the ground line. This is a hint for those who would like to turn "riders" into "dwarfs" but do not know "how to do it." The kinds grown are Royal George Peach and Victoria Nectarine.

The early vinery was showing fruit in abundance; the laterals strong and foliage of good size and substance, altogether being in such condition as one expects to see them in the hands of such a master of the art. On the floor of this house were a number of pots of French Beans, Osborn's Forcing being a favourite.

On back shelves in another house was a quantity of Black Prince Strawberries coming into flower, that variety and Viscomtesse Hericart de Thury constituting the bulk of what are grown in pots at Wortley, and for all-round work and purposes certainly the Viscomtesse is difficult to surpass. *Lapagerias* are well grown at Wortley, having a span-roofed structure standing north and south for their accommodation. Shoots like Asparagus are again making their appearance, and next summer and autumn will produce their clusters of waxy-white and crimson-coloured bell-shaped flowers. The principal plant more resembles (about the base) a bundle of faggots than ought else, so abundant and thick are the shoots.

In the cool Orchid house *Celogynes* were in strong force and in full flower. One variety appears to be more floriferous than another which has darker green leaves and pseudo-bulbs, but for intrinsic beauty, as they appear to the eye, the darker-hued one is the most preferable in my opinion.

The lovely pearly-white *Odontoglossum pulchellum* was flowering very freely, and *O. Alexandrae* was there in quantity, as well as varieties of *Cypripediums*.—J. UDAL.

#### KITCHEN GARDEN.

THE weather is still cold, and it will be a late spring. The dry condition of the soil has lately induced us to sow or plant several early crops, but there is no warmth in the soil, and probably the crops put in during March may in every way excel those planted in February. March, however, is a kitchen gardening month, and we must now be prepared to work on every favourable opportunity.

**EARLY CARROTS.**—Many of our readers who have no frames or glass protection to use in getting up their first crop of Carrots will be eager to sow as soon as possible in the open, and this may be done any time now. Carrot seed, and the young plants as well, are very hardy, and if sown in light well-drained soil they will stand much severe weather without injury. We have always sown our early Carrots by the end of February or during the first week in March, and we never knew them to fail through being sown too early. The ground for their reception should be deeply dug and broken. A little lime or soot should be dug in, but no manure of a rough character. When the soil is not rich enough from previous manuring, we prefer artificial manure, strewing a little guano

along each side of the rows as soon as the plants are thinned. This is an excellent stimulant, and it also helps greatly to keep the grub off. The rows should be 16 inches apart, and the drills about 1½ inch deep. It is a good plan to place some old sandy soil over the seed, and when all has been completed a roller should be taken over the surface, as Carrots delight in a firm soil. We are always very particular in sowing the Carrot crop in question, as we find the roots from this crop useful until quite late in autumn. The French Horn is the earliest, then comes the English Horn, which is larger, and both should be sown now.

**RADISH.**—The first week in March always finds us sowing our earliest Radish in the open, and sowing may now be general. Wood's Early Frame and French Breakfast are two of the best to sow at this time. A small bed a few feet square will furnish a great many roots, and more need not be sown at present. The ground should be light and not too rich. When spring Radishes are sown on very rich ground they are sure to make more top growth and smaller roots than they ought to. Sow the seed thinly broadcast, and covered to a depth of half an inch. Small birds are very fond of Radish seed, and it is advisable to place a few wood hoops over the bed, covering with netting. All small seeds may be treated in this way.

**TURNIPS.**—Early Milan is the earliest variety by many days, and it alone should be sown as a first crop. There is very little use in attempting to sow Turnips in February, but we begin as soon as March is in, and although those sown now will flower before very large roots are formed, they will produce sweet little roots for a short time. Only a row or two need be sown now, and the quantity may be increased fortnightly. The soil must be moderately rich, and the rows about 18 inches apart. A few short rows on a south border will be found more satisfactory than any out in the open quarters. Sow thinly, and when the soil is dry.

**PEAS.**—Dust those above ground frequently with soot or lime; stake them as they come through the soil, especially in windy positions, as they will benefit by protection. A general sowing of those sorts which are to bear by the end of June and during July should now be made. Wrinkled varieties which are apt to decay in damp cold soil in the early part of the year may now be sown freely. Practise the trench system from this time onwards. Throw the soil out to the depth of 18 inches and about the same in width, then place a layer of manure to the depth of 5 inches or 6 inches at the bottom; put a layer of soil over this, sow the seed, and finish off by placing 2 inches more soil on the top of the Peas. After this, no matter how hot and dry the weather in summer may be, the Peas will continue growing and bearing abundance of fresh pods and tender green Peas. Nothing detracts more from the flavour of Peas than dryness at the root, and deep sowing is the only way to guard against this. When trench Peas are earthed up this is simply done by levelling in the soil along the edges, and when this is completed the roots will be so far below the surface that no ordinary amount of drought will injure them in the slightest. Telegraph, Pride of the Market, and Stratsgem are three splendid main crop Peas. They are all excellent for exhibition. Champion of England and Veitch's Perfection are two more of exquisite flavour, and they should also be sown in March. Do not be in a hurry to plant out Peas which have been raised under glass, as the weather is not in their favour yet. Indoor sowing is only advantageous when transplanting is done successfully.

**POTATO PLANTING.**—Early varieties of the Ashleaf type may be planted on south borders, but no choice varieties should be trusted out yet. If the ground has been dug over before it will be nothing the worse of being turned over again, and planting may be done as digging goes on. Keep the rows from 20 inches to 2 feet apart, and from 1 foot to 16 inches from set to set. If the soil is friable and good a little artificial manure will benefit the crop, but where the soil is heavy and stiff a liberal introduction of leaf soil or any old refuse will be advantageous. No attempt should be made to plant the whole of the early crop for another fortnight or more, and those planted now should just be sufficient to keep the supply going after those planted in sheltered places lately are finished. Admit plenty of air to Potatoes now swelling in frames. Water sparingly, and take the lights off when the sun shines briskly.

**TOMATOES.**—Where plants are wanted for turning out in May sow Laxton's open air variety at once. It is excellent for open air culture. Pot young seedlings. Never allow them to become crowded or root-bounded while young. Keep plants coming into flower full in the light. Give them plenty of liquid manure, but do not be too free with the syringe. First-rate early crops may be obtained from plants in 10-inch pots, and those which are growing freely should be put into this size as soon as possible. Our earliest plants this spring are those taken off as cuttings and rooted last October. They surpassed the seedlings. A first sowing of many vegetables may now take place. The main crop of Brussels Sprouts should be put in, early and late Cauliflower, Cabbage, and Leeks. We fork up one of the narrow borders near the walk in the kitchen garden, open drills across, and sow the whole of these together. The rows are about 1 foot apart, and the plants are drawn from these and put into their main quarters. Unless Brussels Sprouts have a long season they will never develop fine and abundant sprouts. Spread out the general stock of seed Potatoes, and let them have plenty of light. Look over stored Carrots and Beetroot; remove decayed roots, and break off any young growths which may have formed.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Early Houses.*—As the trees have been brought forward almost entirely under the influence of fire heat, red spider will soon appear on those near to the hot-water pipes, and as this

is the worst insect we have to deal with in this department, the syringe must be vigorously applied until the pest is destroyed. Dryness at the roots and a dry atmosphere are favourable to its spreading rapidly, whilst the check to the trees consequent on its attacks is often the cause of the young fruit falling off. As an aid to the syringe every part of the border inside should be well mulched with short horse manure, and thoroughly soaked with tepid water a few degrees above the mean temperature of the house. Proceed with disbudding, thinning, and tying in the young shoots from the lower parts of the bearing wood, and pinch back where it is thought desirable to form spurs. Ventilate early and gradually as the temperature rises, reducing it by degrees, and endeavour to make up for lost time by running it up to 80° with sun heat and moisture after closing for the day. A night temperature of 55° to 60°, according to the condition of the weather, until after the stoning process is over, will be quite safe. The day temperature from fire heat should range from 60° to 65°, and 70° to 75° with sun.

**Succession Houses.**—Trees now in bloom may have a free circulation of air, with just sufficient fire heat to prevent sudden depressions of temperature, maintaining 50° at night, and a few degrees less on cold nights. A temperature of 50° to 55° will be suitable in the daytime, advancing to 60° or 65° from sun heat, with a free circulation of air. Shake the trellis frequently, pass the camel's-hair brush or feather over the flowers once a day, and give extra attention to the shy-setting varieties by conveying pollen from others that produce it in abundance, as for instance Royal George. Keep the paths well damped on fine days, and be more sparing of water when the weather is dull and cold.

**Late Houses.**—Retard the blossoming in houses inefficiently heated by abundant ventilation with a view to escape injury from spring frosts. Keep a keen eye on the borders; have them mulched and moist. Lack of water at the roots early in the season is the cause of many failures in the culture of Peaches.

**CUCUMBERS.**—Tying, stopping, and thinning the shoots should be regularly attended to, and all superfluous and misshapen fruits removed. Plants in full bearing will require liberal supplies of tepid liquid manure. Syringe the plants twice a day in bright weather, which will keep red spider and fly in check, and close the house with plenty of atmospheric moisture at 2 to 3 P.M. Keep the evaporating troughs filled with liquid manure, the ammonia vapour being beneficial to the plants and inimical to insects. Young plants now making vigorous growth, and having been stopped previously on reaching the third wire of the trellis will need to have the growths trained regularly and not too closely over the trellis. Add some more soil to the hillocks as the roots push through the soil, repeating until the allotted space has been filled. See that the linings of dung-heated frames or pits are duly attended to, having a quantity of fermenting material in reserve for application as needed.

**MELONS.**—Occasional glimpses of sunshine with which we have lately been favoured have helped the Melons wonderfully, the plants making satisfactory progress. Nevertheless, every effort must be made to compensate for lost time through cold and the long absence of sun by making the best use of bright sunny days for entrapping the sunbeams by early closing, and affording a congenial condition of the atmosphere by damping available surfaces or syringing the plants. The plants growing in hot-water-heated pits over dung beds, and which have been stopped at the third leaf some time back, will now have made some laterals, about four of which should be trained over the surface of the bed, and stopped when they have made about 18 inches to 2 feet of growth, or when they are about 1 foot from the sides of the pit, which will result in the pushing of sub-laterals or fruit-bearing shoots that may be stopped at one joint beyond the fruit, after which, with the necessary stopping and thinning of the shoots, the plants may be allowed to furnish the allotted space. Fertilise the blossoms on fine days when the pollen is dry, and maintain, as far as practicable, a rather dry atmosphere whilst the plants are in that stage of growth, and until the fruit is set. When the plants in the Melon house have reached the fourth wire of the trellis they must be stopped, and the shoots trained horizontally to the wires. Earth up any young plants that may require it, and shift into larger pots before they become root-bound, or plant out before that condition is reached. Successional sowings and plantings must be made according to the requirements of the establishment in order to maintain a succession equal to the demand.

**FIGS—Earliest Forced Trees in Pots.**—The first swelling of the fruits will soon be completed, when they will remain apparently stationary for a considerable time; and as this is the most critical stage in their culture every care must be taken not to give a check, whether caused by excessive heat or want of moisture will, in all probability, cause them to drop when the time arrives for them to commence their last swelling. Should the weather prove mild the temperature may be kept at 60° to 65° at night, but if cold 5° less will be found safer. What is lost at night may be gained in the daytime by closing with plenty of heat and moisture, when a rise of 10° to 15° may be indulged in without producing a weak or elongated growth, keeping through the day with gleams of sun at 70° to 75°. Copious syringing on all favourable occasions will be absolutely necessary, as red spider is almost sure to attack the leaves in close proximity to the pipes. It is very important that a steady supply of tepid liquid be afforded the roots, as Figs in full growth require generous support, providing it does not remain stagnant, which can hardly happen when the pots are stood on brick piers well above the floor of the pits.

**Succession Houses.**—Attention to thinning and disbudding must be given if there is any probability of the growths becoming crowded, stopping at the fourth or fifth leaf if it be thought desirable to form spurs, from which the second crop of fruit will be obtained. Syringe the trees twice

a day, and keep the mulching constantly moistened with diluted liquid manure.

**Young Trees in Pots.**—Shift those intended for next year's forcing, and place them in or over bottom heat. Shade slightly from bright sunshine for a few days until they show signs of having taken to the new soil, when they should be fully exposed to sun and light.

#### PLANT HOUSES.

**Nepenthes.**—Plants that have grown tall and ceased to pitcher freely should be cut down to within 4 or 5 inches of the base. If done at once they will soon break into growth, and before the season is over will be well furnished and pitcher freely during the autumn and winter. It is a mistake to allow these plants to run up until they become pitcherless, for if pinched from time to time when growth has been made a few inches long they will continue growing and pitching for years without being cut back. By this means a regular supply of pitchers is secured the whole year round, and large specimen plants are the result. Plants grown on the pinching system, or young ones that need larger baskets, should be placed in them at once. The whole of the old ball must be carefully lifted out of the one in which it is growing and placed into the larger one without disturbing the roots. Previous to this the baskets should be liberally drained and a layer of the compost placed at the base; the remaining space should be filled with peat fibre and charcoal, and the surface covered with a layer of sphagnum moss in a living state. These plants will grow well in loam, charcoal and sand, sphagnum moss and peat in equal proportions, but after trying these and other mixtures the one advised above is preferred for its lasting qualities. These plants should be liberally syringed and never allowed to suffer by an insufficient supply of water. If necessary to increase the stock of these plants the stems from those cut down should be cut into lengths, two joints for each cutting being sufficient. Insert these singly in 3-inch pots filled with sphagnum moss and a little coarse sand for the base of the cutting to rest upon. The top of the cutting only should be left out of the moss, then watered and plunged in brisk heat and covered with a handlight. It is necessary to keep them airtight until they are rooted. The stems cut into lengths root freely, but the greatest difficulty will be experienced in hardening them to bear full exposure in the atmosphere of the house in which they are to be grown.

**Bertolonias.**—These are charming foliage plants when well grown, but to do them full justice they require to be kept in a case or covered with bell-glasses in the house in which they are grown. This, however, is only necessary when a liberal system of ventilating is practised. They stand exposure well in a close moist shady house where the ventilators are seldom opened. To have them in the best condition cut them over at the present time, and the heads or side shoots may be rooted snugly in small pots. The cuttings root quickly in the propagating frame or under bell-glasses if shaded from the sun and kept in brisk heat. They should be inserted in sphagnum moss and sand; to this peat fibre may be added after the plants are rooted and need larger pots. After the plants are re-rooted, with good treatment they will grow rapidly and develop large beautiful leaves. The old plants from which the head or cuttings have been taken will break again into growth, and very often make very fine plants if they are potted deeply, so that the young shoots can root out of their stem and thus become independent of the old stool.

**Sonerilas.**—Charming small-growing stove foliage plants. To have these in the best condition through the summer all the growing shoots should now be taken off and rooted. The cuttings of these plants root very well under the same conditions as Bertolonias, only they should be inserted in sand, as they can be lifted out more easily than when a mixture of moss and sand is employed. When rooted pans can be filled with the compost advised for Bertolonias, raising it well above their rims, and the young plants should be planted over the surface of the pan about 1 inch apart. These must be kept close for a time until they are established, and then gradually exposed in the stove. By this treatment the whole pan is furnished in a very short time, and very few small-growing plants are more beautiful.

**Fittonias.**—These plants are very useful and very few are more effective when used in association with mosses for furnishing the outer edge of baskets or large vases used for room decoration. These strike easily in a close propagating frame, and when rooted may be grown in any light open compost in boxes or pans and lifted out when desired. They certainly last longer if established in small pots and plunged in boxes amongst sand or moss to prevent them drying. Well-furnished pans well elevated in the centre are very pleasing in the stove during the summer.

#### THE FLOWER GARDEN AND PLEASURE GROUND.

**PROPAGATING BEDDING PLANTS.**—**Solanums.**—These are almost indispensable in the sub-tropical garden, beds filled principally with one of such handsome, bold-foliaged sorts as *S. robustum*, *S. Warscewiczii*, *S. giganteum*, *S. marginatum*, and *S. pyracanthum* rarely failing to attract admiration. All are raised from seed, and as they are slow-growing the seed should be sown at once in order to have them sufficiently large to be effective when first planted out. The seed may be sown in pans or pots filled with light sandy soil, lightly covered with a little fine soil, and then stood on or plunged in a fairly brisk bottom heat, covering closely with glass till the seedlings appear, when it must be removed, and the plants be encouraged to grow sturdy. When large enough to handle rather more than the requisite number may be potted singly into 2½-inch pots, or they may be pricked off thinly in pans of light and fairly good soil, potting them off singly before they become crowded. They must be still be kept growing in a fairly warm house, being given a final shift into 6-inch pots

before they become badly root-bound, giving them fairly rich loamy soil. During May they are best kept in a cool house or frames, an early exposure to our trying climate having the effect of stunting their growth, and from this they do not readily recover.

*Wigandia caracasana*.—This noble sub-tropical plant in its earlier stages of growth is slower even than the Solanums. The seed is very small, and should therefore be sown on the sandy surface of a pan of fine light soil, plunging this in hothed, shading heavily, and moistening the surface very carefully till such times as the seeds are germinated. The seedlings when quite small, or before they are large enough to handle, must be pricked out in a pan of fine soil, this being easily managed with the fine point of a dibble, and they will require good attention in the way of shading and gentle waterings. Later on they may be treated similarly to the Solanums.

*Eucalyptus globulus*.—Now is a good time to sow seed of this tall-growing and fairly ornamental sub-tropical plant. Sown in pans or pots of light sandy soil, and plunged in heat or merely stood in a forcing house, covering with glass, shading from bright sunshine, and kept uniformly moist, the seed soon germinates, the subsequent treatment being the same as recommended for the Solanums. Any plants that may have been kept in small pots through the winter should be given a liberal shift, good loamy soil being used, and this will be the means of much improving their size and appearance before they are wanted for the flower garden.

*Acacia lophantha*.—Although not particularly handsome this is still a favourite green-foliaged plant with many decorators, being both available for planting or plunging in the mixed beds, and subsequently for conservatory and house decoration. It is raised from seed, and as these are very hard they should be soaked in warm water for several hours, or till such time as they have swollen considerably. Then if placed singly into small pots filled with warmed soil, plunged in a brisk bottom heat, and soaked with water of the same temperature as the hothed, the seeds germinate in a few days. When growing strongly they should be given a liberal shift, and be transferred to a greenhouse before they are drawn and weakened. For large beds last year's plants are best. Any fairly rich soil will grow them well.

*Ferdinandia eminens*.—This is a tall-growing and highly ornamental sub-tropical plant, and very effective in masses. They may be raised from seed, and otherwise treated similarly to the Solanums; or if there are any stock plants short lengths of firm wood will strike readily in heat, and soon grow to a good size if kept well attended to.

*Polynnia grandis*.—A few plants of these are usually kept through the winter, the stems being cut into short lengths and struck in heat. If duly potted and given a liberal shift, using a fairly rich loamy compost, the plants soon attain a useful size, and if finally planted in good soil they will grow 6 feet or more in height, and a mass of them are very imposing.

*Ficus elastica*.—Where tops of these are available they may be struck to a length, say, of about 12 inches, without the loss of the leaves, and later on they will be found very useful in the flower garden. These long pieces are most surely rooted by notching or cutting them half through, binding moss round the wound, and if they are then placed in heat and the moss kept regularly moistened, roots will soon be emitted into it, and these rooted tops can then be severed and potted safely. We have also frequently succeeded in striking the tops and side branches with a heel attached in a brisk bottom heat with the loss of but few leaves. Short lengths of firm wood with a leaf attached, also strike readily in heat, but if put in at the present time the plants resulting would be of no service in the flower garden this season.

## THE BEE-KEEPER.

### REVERSIBLE FRAMES.

SHALL I adopt reversible frames? This is a question which has no doubt been asked by most bee-keepers who use moveable frames of any description, and not a few of them have, it is to be feared, answered somewhat too hastily in the affirmative. A few weeks ago in talking to a bee-keeper who has upwards of a score of stocks, the majority in moveable frame hives, I asked him whether it was his intention to adopt the reversible frame, and he answered "No! it is against Nature to reverse the inclination of the cells." Now it does not seem to me of any material importance whether a given practice is against Nature or not, so that we fully realise the responsibility which attaches to ourselves immediately that we upset the arrangements of Nature. If we interfere we do so knowing that if failure follows our efforts we alone are to blame for unwisely interfering in the internal economy of the hive; if we succeed we have our reward in increased profit and pleasure. We may, therefore, consider this reply to be altogether beside the question, and may discuss the reversing theory from a more practical point of view.

It is well known amongst bee-keepers of any experience that bees always store their honey at the top of the comb, leaving the more central and lower parts free to a great extent from honey for the use of the brood. Now this is apparently considered by many an objectionable habit, because the size of the brood nest is seriously diminished, and honey is stored in the body hive—from which it cannot be taken in a form fit for sale as comb honey—instead of in the supers placed ready to receive it. Here is the opportunity for reversing, and this being done the bees, strong in their determination not to have the honey at the lower extremity of the comb, at once set to work to remove it and place it in its proper position above the brood nest; but as the cells at the top of the comb are occupied with eggs and brood in all stages of development, there is no room for the honey, which is therefore carried and placed in the supers. For a day or two after the manipulation extraordinary progress is made in the supers, and the apiarian begins to congratulate himself upon the success of his experiment, but suddenly a partial stoppage takes place, and honey comes in more slowly than previous to the operation.

Now if we consider what has taken place this will not cause any surprise, because a quantity of honey being stored in the hive a removal takes place, and this is done more speedily than when the flowers have to be visited and fresh honey gathered; this continues until the supply in the body hive is exhausted, when, as a natural result, honey comes in more slowly than ever, because more bees are required to stay at home to "set the house in order" after the strange disarrangement. The cells are often pared down to the midrib, or at least their inclination altered, and all this entails a vast amount of exhaustive toil on the worker bees, which are thereby unable to go forth to the fields and gather honey in their wonted number. In reality to get, say, ten pounds removed from the body hive to the supers, we lose five, which at least might have been got from the fields without difficulty if the bees had not been engaged at home. Surely a roundabout way of getting profit! There is one good result from the manipulation, but it is only temporary, and constant reversing must take place to render it of continued use—the brood nest is enlarged so that the queen is given more room for egg-laying, and the population of the hive is to some extent increased, and the desire to swarm diminished; but no sooner does the brood hatch from the top parts of the comb than the cells are again filled with honey, thus again necessitating the reversing process if lasting benefit is to accrue from its adoption. If, however, there is this necessity for artificially—may I say—enlarging the brood nest, one of two things is apparent, either the supering management is faulty, or the capacity of the hive is too little. But let me give the nett result from this reversing of combs, which appears to be that a temporarily enlarged brood nest is obtained, that a great amount of unnecessary labour is imposed upon the bees, and instead of getting 10 lbs. of honey in the super and 10 lbs. in the hive, we get 10 lbs. in the super, and much less than that amount in the hive itself, probably only half at the outside.

In the case of skeps, however, there is one other advantage which accrues from reversing the hive itself, and this is that a much larger surface is available for supering purposes and this is a decided advantage, for the ordinary 4-inch hole causes no little inconvenience when the hives and supers are crowded with bees all eager to work, but the hive being reversed the whole breadth of the comb lies ready for the super, but even to gain this advantage I should hesitate to adopt the practice. On the whole then, reversible frames are, as far as I am able to judge, of very doubtful utility, and should only be adopted on a small scale by way of experiment, when, if the result is, as I anticipate, unfavourable, no great loss will be occasioned, while if favourable they can another year be more extensively adopted.

There is one other improvement upon the above idea to

which I may briefly call attention, as by this plan one of the objections urged against the reversing principle is obviated. It appears to me to be greatly superior, both in principle and practice, to the other more troublesome and time-losing manipulation. In order to give some idea of the plan I will take the Stewarton hive as being the one which lends itself most easily to the adoption of honey and brood-displacement. Its principal use will be at the end of the honey flow, and at no other time ought it to be attempted, when a super is unfinished, and there appears to be no prospect of its being completed in the natural way. Suppose, then, the honey flow being over, we have a Stewarton hive composed of three body boxes and a super not complete enough for removal. We first ascertain if the top body box contains honey sufficient for our purpose, and if so we remove it and place it without reversing it beneath the other two boxes; the brood nest will thus be at the top and the honey below, with the result that the latter will be carried into the super, which will thus be completed without entailing any great labour upon the bees, such as cutting down the cells and building them up again, thus doing away with a great amount of exhausting labour, and with this additional advantage, that the bees are not kept at home when they might be gathering in the fields. This is a suggestion only, and must be tried as an experiment with the sole endeavour to get unfinished supers completed. In the course of the present season experiments with reversible frames on a large scale will be made, and a means will thus be afforded us of gauging their practical value. At present my verdict must—after getting information from every available source—be, that they are of very uncertain utility, and not likely ever to come into general use amongst practical apiarians. There are always, however, certain bee-keepers who love novelty, and are ever ready to adopt the latest so-called improvements, only to discard them again, and return to proved and valuable appliances. No displacement of the relative positions of the honey and brood will come into practice in all probability, but on exceptional occasions it may be advantageous to effect such displacement when it can be done without reversing the combs. Reversing of combs will, in a few years, be entombed with many other inventions of a like nature, and will be remembered only as a glaring instance of the strange infatuation which possesses a not inconsiderable section of the bee-keepers of the present day.—FELIX.

#### BEE NOTES.

**BALLOTING FOR HIVES AT COUNTY BEE-KEEPERS' MEETINGS.**—At the annual meeting of the Worcestershire Bee-Keepers' Association, held at the Guildhall, Worcester, on the 20th inst., Mr. J. Hiam, Astwood Bank, was fortunate enough to win one of three bar-frame hives allotted to the members annually. As there are 266 members, only a few of whom have had hives, the chances are about eighty-five to one; or, to put it another way, if we all live eighty-five years longer, and there are as many members and the same quantity of hives distributed annually, we should be entitled at the end of another eighty-five years to another chance. Not long to wait!

**TOMTITS v. BEES.**—Before any replies are sent in answer to "G. H. P.," page 162, let us be clear as to the bird referred to. From the description of the habits of the bird and from the remark, "the black-headed tomtit," I have no doubt that "G. H. P." refers to what is locally known here as the "Tom Collier," or ox-eye (*Parus major*). I am well aware that these are particularly fond of bees, and have often watched them pick up stray bees and pull them to pieces, and pick out the dainty morsels from the inside of the bees, discarding the wings, legs, and outside. But this much I can safely say, that I have never seen them kill my bees, although I will not say that they do not. The bird I referred to, and which there could be no mistake about, as I had one at the meeting referred to, which was shown in his little domicile purposely provided for him, where he sleeps every night, going about his business during the day, was the bluetit (*Parus caeruleus*), which is always understood as the tomtit in this locality, and by reference to many books. If I used the word "harmless," it was with reference to killing bees. I know they have a decided relish for many kinds of fruit, and the worst of it is, with Apples and Pears, they like to taste too many; it would not matter if they would stick to one and finish it. On the other hand, they are of immense value in destroying caterpillars, aphides, scale, red spider, &c. I could go thoroughly into this subject from observation, but it would occupy too

much space and time. Knowing their value, I encourage them. I have had exactly three dozen reared in the past three summers in an old tin teapot fixed in a Plum tree for them.—J. HIAM.

#### TRADE CATALOGUES RECEIVED.

Osman & Co., 14, Windsor Street, Bishopsgate, London. E.—*Wholesale Price List of Nurserymen, Seedsmen, and Florists' Sundries, 1886.*  
J. C. Vaughan, Chicago.—*Catalogue of Tools and Bulbs.*  
Hogg & Wood, Coldstream and Duns, N.B.—*List of Agricultural Seeds, Spring, 1886.*  
Edmund Philip Dixon, Hull.—*Farm Seed Catalogue for 1886.*  
H. Gusmus, Rosenheim, Bayern.—*List of Alpine Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Address (R. R.).**—The Secretary of the United Horticultural Benefit Society is Mr. John F. McElroy, The Gardens, Moray Lodge, Campden Hill, Kensington, W.

**Specimen Glasses for Roses (*Juvenis*).**—We do not understand to what glasses you refer, nor do we see anything concerning them on the page you give. Write to the Editor of the "Rosarian's Year Book," the Rev. H. H. D'Ombraim, Westwell Vicarage, Ashford, Kent.

**Artificial Manure (C. W., Coventry).**—As we have many times stated, we cannot possibly undertake to analyse either soils or manures. The sample sent resembles phosphate of lime. Apply a portion in differing quantities to Cabbages or grass and note the results. We do not suppose that 3 ozs. to the square yard would do any harm. About that quantity we think would be good for Potatoes and most other crops, but proceed experimentally.

**Rhubarb from Seed (D. J.).**—Plants can be raised from seed quite easily by sowing in the open ground during fine weather in April. It is a good plan to sow in drills a foot apart, placing a few seeds at intervals of a foot, then when the plants appear thin them out as may be needed, allowing one to remain. These plants grow to a good size the first year, and an idea can be formed as to which are likely to be the best, there being usually considerable variation, and the worst can be removed. The others can either remain for affording produce the following year, or be taken up and planted at wider intervals for forming a permanent bed.

**Sparrows and Gooseberry Buds (G. S.).**—Undoubtedly these birds destroy the buds, and we have known bushes ruined by their attacks. Where the pests are troublesome it is a good plan not to prune till late in the spring, as we have known autumn-pruned bushes divested of every bud in the winter; but they are seldom all destroyed on unpruned bushes. Some persons use worsted, and if this is stretched from the ends of the branches so as to form a rough network, it is often, but not always, efficacious. Dusting the bushes when they are quite wet, as on a still misty day, with freshly slaked lime is an excellent bud preservative, it also keeps the branches free from moss, and the lime falling to the ground is good for the trees in most if not in all soils.

**Planting of Gladioli (*Ebor*).**—Certainly Gladioli may be grown as "far north" as where you reside, and are, in fact, splendidly grown a great deal further north—in Scotland. They are grown as well in the north as the south, if not better. The time for planting should be governed by the weather and the consideration of the soil, not by the almanack. We have planted in February in light soil in a free dry state, and in April in strong land with equal satisfaction. Any time from the middle of March to the middle of April is suitable, always taking advantage of favourable weather, when the land is dry on the surface. An article from an experienced cultivator, "D., Deal," on the culture of these beautiful but often fickle flowers, will shortly be published.

**Adiantum cardiolochlana Unhealthy (J. T. S.).**—The plant may need repotting or the drainage may be insufficient, and your best plan, if it has not been repotted for some time, will be to turn it out, removing the whole drainage and a little of the old soil, especially if it seems to be sour. Have a thoroughly clean pot of suitable size, well drain it with clean potsherds to one-third of its depth, and repot the Fern in fresh fibrous peat and a small proportion of light loam, with a liberal admixture of silver sand. Keep the plant in a close warm house for a week or two, and give only sufficient water to render the soil moist until growth is advancing. Do not let the plant be fully exposed to the sun at any time, and avoid placing water on the fronds, though a moist atmosphere is necessary.

**Peas for Use (B. L. E.).**—The question of varieties to grow is often very much a question of sticks for supporting them. A great number of varieties are not necessary for succession. A succession can be maintained by growing a few rows of many sorts, but not better than growing several rows of a few varieties. We know a gardener who sows twenty quarts of Peas annually—two of William I., fourteen of Champion of England, and four of Ne Plus Ultra. With the last sowing of the first named he sows the second, and with the last of this he sows the third. As soon as the plants of the Champion are visible he sows more rows. The succession is unailing and the produce of the first quality. His last sowing of Ne Plus Ultra in June is three or four times the extent of spring sowings, because the rows are not so productive in late autumn as in summer. He gathers Peas from the end of May till the end of November. This is very plain practice, perhaps too plain for you, but the gardener who adopts always has "Peas for use" in season.

**Market Gardening (H.).**—It is a matter requiring very careful consideration. The distance from market will tell considerably upon the proceeds of the sale, and the question will be whether it would not be cheaper to take the produce the whole distance than to take it a fourth of the whole to the railway and then have to pay carriage. This must be ascertained by a comparison of rates or cost of the two modes of transit, but as there is little means of keep for horses, we think the railway would prove the cheapest and quickest. The glass would not bring in much, as the vineries are planted with varieties that would have to be forced so as to come on early in May or June if they brought paying prices in the London market, but you might find better prices at local shops were the Grapes ripened successionally; indeed we should not expect to realise more than £50 from the glass, though you might derive some profit from growing plants. As not more than half the wall trees can be depended upon it will lower the value proportionately, and the value of the land outside will depend upon its availability for crops. Something could be made by keeping pigs no doubt, and you will need to take into consideration the facilities of procuring manures. According to the statement you give we think the rent high, especially as the fruit trees are in poor condition, and will need a considerable outlay before the wall can be made remunerative, the lease not being long enough to allow of any great improvement without compensation at its expiration. We should certainly make a calculation very carefully before committing yourself, our opinion being that £10 per acre, taking the concern as it stands, would be a sufficiently high rental under the circumstances, beyond which we should not go without there are other advantages, which do not appear to us from a careful consideration of your letter. Trade is not brisk, nor likely to be for some time, and expenses are heavy.

**What is a Pippin? (Oxon).**—We publish your postcard question, and answer it from the last edition of the "Fruit Manual." The word Pippin is derived from the French Pepin, the seed of an Apple, and in its earliest signification meant an Apple tree raised from seed in contradistinction to one raised by grafting or from cuttings. Thus Leonard Mascall, writing in 1572, says, "Then shall you cover your seedes or pepins with fine earth so sifting al over them;" and "when the winter is past and gone, and that ye see your Pepins rise and growe;" and again, "When so ever ye doe replante or change your Pepin trees from place to place, in so removing often the stocke the frute there of shall also change; but the frute which doth come of Grafting doth always kepe the forme and nature of the tree whereof he is taken." It is evident from this last quotation that Pippin is synonymous with seedling, and is used to distinguish a tree raised directly from seed from one that has been raised from grafts or cuttings. The Golden Pippin, which, by the way, was raised in Sussex, where Mascall also was born, means simply Golden Seedling. But there was another meaning attached to the word. In "Henry IV.," Shallow says to Falstaff, "Nay, you shall see mine orchard; where in an arboure we will eat a last year's Pippin of my own grafting." And this is interpreted by what Sir Paul Neile says in his "Discourse of Cider," written in the time of the Commonwealth, wherein speaking of "Pippin cider," he says, "For by that name I shall generally call all sorts of cider that is made of Apples good to eat raw," and that is evidently the signification in the above quotation from Shakespeare. Coming to more modern times, we have the word kernel, which is the English equivalent of Pepin, also used to signify a seedling Apple tree; as, for example, Ashmead's Kernel, the seedling raised by Dr. Ashmead of Gloucester; Cook's Kernel, Knott's Kernel, and many others.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (E. J. Bath).—The fungus on the leaves of the Eranthemum was examined by Dr. Cooke and determined to be a new species, which he has named Isariopsis acanthacearum. (W. R.).—The Orchid is Dendrobium luteolum, a useful winter-flowering species; see the figure on another page. It is a native of Moulmein, whence it was sent by the Rev. C. S. Parish to Messrs. Low of Clapton. (J. S.).—Cytisus filipes.

**Selling Honey (Eastern County).**—Undoubtedly your best plan would be to advertise the honey, and at a moderate price you would soon find purchasers.

#### COVENT GARDEN MARKET.—MARCH 3RD.

#### LAMBING TIME.

FAT lambs may still be regarded as a profitable item in farming accounts, and now that lambing time is almost ended on the home farm we are making strenuous efforts to assist growth and do all we can to promote early development into a marketable commodity of as many lambs as can be spared for early fattening. At the outset this is best done by affording a liberal diet to the ewes, or, rather, it should be mentioned that the ewes are never suffered to fall into low condition, but are kept fairly sleek throughout the year. By a moderate addition of corn or cake in August we are able to manage early breeding, and remember that a ewe in poor condition is always slow and backward in breeding. Why is it that so many ewes are pressed upon the markets in such wretched plight as we saw them last autumn? No doubt the answer generally would be that, owing to the drought, pastures had become bare and flocks had suffered privation. But then we may well inquire farther, if such privation was unavoidable? What is there to debar one from trough-feeding throughout summer if need be? Sheep do not always take readily to a fresh article of diet, but we may safely take it for granted that bare pastures would soon drive them to racks or troughs, and chaff or straw

would then be eaten readily enough. For such an emergency what could we desire better than a crop of winter Oats? It is generally ripe by the second week in July, it might then be taken, and by converting the unthreshed grain into chaff with the straw, we provide a nourishing dietary to which the sheep take readily enough, and we certainly are then turning the Oat crop to profitable account.

He is a poor farmer indeed who waits till lambing time before making due provision for feeding the lambs. But it is now, while the pressure of such a considerable addition to our live stock is fully upon us, that we probably see most clearly what could be done for them, and attention may usefully be called to the matter now. During the last month or two of the period of gestation the ewes had cake and chaff in addition to grass, but they had only a few roots given them on the grass, the roots being only given by way of change, and not as the principal article of diet. We have repeatedly called attention to the mischief arising from folding pregnant ewes on roots, and we may add here the satisfactory fact that we have not had a single case of abortion this season. That abortion, to a serious extent, is caused by a diet of cold, often frozen roots, has been proved so repeatedly that one cannot but wonder at the repetition of a process that is known to be fraught with such risk. A considerable area of good sound grass pasture was held in reserve from last autumn specially for the lambing; but knowing as we did that the grass alone would not suffice for our large breeding flock, a field of large late Drumhead Cabbage was sown at the end of last April, specially to afford a supply for the flock now. These fine Cabbages have not been protected in any way, and we are happy to say that after exposure to a severe frost of several weeks duration only a few of the very forward have been spoilt. The ewes eat them greedily, and they afford a welcome addition to our favourite mixed diet. Two fields of Swedes and White Turnips have also been left out to the frost in order that green tops might be had for the flock, and no roots have sustained any harm, except some in which holes were pecked by rooks and pigeons.

Of green crops for spring folding Rye, Rye Grass, Clover, and the mixed seeds of alternate husbandry, Trifolium, Winter Tares, Sainfoin, Lucerne, and Spring Tares, all afford a rich and bountiful supply in rapid succession, and it is by the skilful culture of such crops for the flock that we are able to bring the lambs and hoggets to early maturity, and to maintain the ewes in a sound healthy condition. By systematic folding upon the land for the consumption of such crops, we also manure the land in the best and most economical manner. It has been said truly enough, that any farmer would prosper who could enrich the land effectually by the manure of live stock, making a profit of the stock and manuring the land gratis. By live stock we certainly here mean sheep, for we decidedly consider the manufacture of manure in cattle yards, and the general use of manure carts a costly and extravagant process that is only advisable for root culture.

Recently we have repeatedly had a special sort of lamb food brought to our notice, and after a careful examination of samples we have definitively decided to give it a trial. It consists of a mixture of crushed food, among which one may readily detect Peas, Beans, Oats, bran, malt, linseed, and several sorts of oilcake, and is apparently an admirable mixture of pure wholesome nourishing food, which lambs of a month old are said to begin eating freely. We can see at a glance that it must be nourishing, and if it only proves sufficiently so to accelerate the early maturity of our lambs in an appreciable degree, from a profit and loss point of view it will prove an acceptable addition to our mixed diet. Lambs, however, should be given fresh food with much caution, a small quantity at first, and a gradual increase as the young animals are able to bear it. Perhaps our best safeguard is to let them run forward on young Rye or Grass, and then careful trough-feeding corrects any tendency to scouring, and rapid growth is accompanied by a plump healthy condition.

## WORK ON THE HOME FARM.

During the last eight or nine months we have been getting a stock of sows for breeding purposes. We have managed to get together thirty useful animals, and five of them have just given us our first instalment of spring pigs, which generally prove profitable, and owing to the widespread ravages of swine fever there is likely to be a brisk sale for them. While avoiding the keeping of a large number of pigs, we certainly find a certain number a profitable investment upon all corn-growing farms; for even when corn is not spoilt by exposure to rain a certain proportion may be turned to good account among the live stock of the farm. In view of this we set apart much more land of Oats this year, and with winter and spring Oats we shall have upwards of a hundred acres. The straw and much of the grain is intended for home consumption by sheep. We have now flocks on four farms, and, notwithstanding foreign competition, they still represent a fair margin of profit, provided a very heavy outlay upon purchased food can be avoided.

Before sowing Clover pure and simple we shall do well to consider if we may not do much better to sow a mixture of strong-growing grasses with it for a two or three-years layer. If the land be clean and in good heart we may certainly do so advantageously, for by judicious folding or the application of artificial manures we may get heavy crops of fodder and effect a considerable saving of labour. This is a matter worthy of our serious attention now more than ever, the only thing in favour of a crop of Clover being the profit that may sometimes be made by the sale of the seed. It is well to let the corn be sown a week or two before the "seeds," as otherwise we are liable to have so much grass in the bottom of the sheaves that the carting and stacking is much hindered. Let especial care be taken to procure all grass seeds from a safe source in order to avoid adulteration. No time should be lost in corn-sowing as soon as the soil is sufficiently dry. An early seed time means an early harvest and an early harvest often means corn saved before rain sets in, and we certainly had this lesson well enforced last harvest. Be on the alert to begin the stirring and cleaning of foul land as early as possible, and if the land is poor avoid a bare fallow. Sow White Mustard, to be ploughed in as soon as the seed pods appear, and if the weather is favourable for a second crop of Mustard by all means sow it to be ploughed in in due course, and thus store the land with fertility in a manner at once simple, efficient, and economical.

FARMERS' CATALOGUES AND HANDBOOKS.—Messrs. Webb & Sons Farmers' Catalogue contains an interesting chapter on "Grass in Alternate Husbandry," together with a variety of information respecting the principal Grasses, illustrated by engravings of the leading useful varieties. Selections of seeds are given for the various geological formations. The Clovers, roots, Cabbages, and the cereals also receive attention, useful chapters being given on "The Field Cultivation of Cabbages" and "The Development of the Ensilage System."

Messrs. Carter & Co.'s Farmers' Handbook is of the customary useful character, and contains articles on "Permanent Pastures," "The Cloven Dodder," "Grass Land's and Dairy Farming for Profit," by Professor John Scott; "Farm Pests and their Remedies," a valuable contribution; "Successful Root Cultivation," which deals with Parsnips, Carrots, Mangolds, Swedes, Turnips, and Kohl Rabi. A few practical remarks are given on "Caraway and Flax Culture in England," "Cabbage as a Field Crop," and much miscellaneous information, with numerous illustrations, completes a very neat annual.

## OUR LETTER BOX.

Cow Swollen (R. C.).—The best answer we can give is to advise you to promptly call in a veterinary surgeon or someone familiar with the ailments of animals. A careful examination appears to be requisite for determining the most suitable treatment of the case.

## REMARKS.

21st.—Fair throughout, but overcast except about noon.  
22nd.—Fine, but not bright, except for a short time about midday.  
23rd.—Cloudy, with sleet, till 11 A.M., fine clear night.  
24th.—Fine, bright, and cold in morning, cloudy afternoon.  
25th.—Fine, but no sun.  
26th.—Fine and bright all day.  
27th.—Fine, with some sun.

An extremely cold week, the temperature being steadily low rather than exceptionally so on any one day. Since February 15th the temperature has only once for a few minutes reached 40°, and there has been frost on the grass every night in February except two, and on each of those the temperature was less than one degree above freezing point.—G. J. SIMONS.

### MIDSEASON GRAPES.

**I**N some cases Grapes will be ripe in April, and in numerous instances in May, but all these must be included as early Grapes, and it is those which ripen in July and August which we regard as midseason Grapes. Throughout the best part of the season most varieties of Grapes may be depended on to ripen in five months after the Vines have been started into growth, and, taking this as a guide, it will be seen that to have Grapes ripe by the end of July the Vines must be started early in March. This is an excellent time for anyone to start their Vines into growth, more especially amateurs. Vines started in December and January require the close attention of skilled cultivators; and it is much the same when starting in February, as artificial appliances must almost be wholly depended upon, but in March, April, and onwards the days are lengthening, the sun gaining strength—natural advantages of the utmost service to the Vines, and I strongly advise all who are not thoroughly experienced to delay starting their Vines until March, and natural aids will lighten their labours and anxieties, wood, foliage, and fruit being produced of such a substantial character as would be quite impossible in the short days. If the vinery is closed now it will be three weeks before the leaves are visible, and they will just be coming out in the early days of April, when forcing is a very simple matter and may be accomplished by all.

In places where vineries are not numerous a long succession of Grapes is generally secured by planting early and late varieties together, such as the Black Hamburgh, Foster's Seedling, and Buckland Sweetwater, with Lady Downe's, Black Alicante, and Gros Colman. All these succeed admirably when started now, as the early fruit will be ripe in July, and if abundance of air is admitted at that time the late varieties are brought slowly to maturity and are thoroughly ripened in good time in the autumn. Everything considered we do not know a better time to start a vinery than the present, and the whole of our vineries will be closed for that purpose this week. At first fire heat should only be employed very sparingly, as the temperature should not exceed 60° by night when it is mild, and a few degrees less in cold nights. Throughout the day a temperature of 65° is quite high enough by artificial heat, but when the sun shines brightly 75° or 80° may be allowed.

It is a decidedly bad plan to allow the thermometer to register 80° or from that to 90° before the ventilators are opened to admit fresh air, and it is always better to ventilate to prevent the temperature rising too fast or too high than ventilate extensively to lower it suddenly. Until the leaves appear, however, ventilating is not a very important matter, but as soon as they begin to develop they are very tender and easily scorched, and the brown spots on Vine leaves, which we often hear of throughout the season, are frequently the result of careless ventilation when the leaves are forming, as

when they are burned then the spots remain the whole of the year.

The first thing requiring particular attention as soon as the vinery is closed is the watering of the roots. When the borders are inside they are, as a rule, allowed to become very dry in winter, with the object of keeping the interior of the house free from damp, and a dust-dry border is not easily moistened. It cannot be done at one watering, and to do it thoroughly it must be watered several days in succession. At first we should give a good application of clean water, to be repeated until we felt sure that the water had been absorbed by the very dry soil at the bottom; we should then follow with a copious supply of liquid manure, and place a deep layer of rich manure on the surface. In a week or so afterwards much clean water would be poured on this manure and be allowed to find its way to the roots; the Vines will then break freely all over, and form very strong shoots and substantial bunches. We have frequently had Vines pointed out to us which failed to start like the rest, and as they were generally at the warm end of the house, where their owner thought they ought to be best ripened and the first to start, their shyness in bursting into growth was very puzzling; but Vines at the hot end of houses seldom receive more water than the others, while their chances of becoming dry are greater, and an extra soaking of the border would cause them to go on right in the majority of cases.

Outside borders, unless they have been protected from the winter rain, are never dry and rarely require watering before closing the house, or, indeed, until summer, but a heavy top-dressing of manure does as much good on an outside border as an inside one, and this should be put on not later than the time the house is closed. It is almost impossible to over-feed Vines, and were they more liberally dealt with, as a rule, we would soon see them with larger foliage and finer developed fruit. A humid atmosphere is also necessary to insure the free starting and expansion of the wood, foliage, and fruit. On dull days the Vines should be syringed at least once daily, and in bright weather they should be syringed twice, about 9 A.M., and from 2 P.M. to 3 P.M. The floor of the house ought also to be kept moist, and if there are any troughs on the pipes they should be filled with water. Under these easily applied conditions it is astonishing what rapid progress Vines will make, and when the atmosphere is moist there is little danger of insects making much headway, which is a very important matter, as, if Vines become infested with insects during the early days of their growth, all hopes may be given up of securing a fine crop of fruit.—A KITCHEN GARDENER.

### LIME AND TOP-DRESSING LAWNS.

IF one thing more than another adds to the beauty of a garden through the summer months it is a perfectly green well-kept lawn. The last two summers have been exceptionally dry, and many lawns suffered in consequence. Last year we noticed lawns quite brown, while others in the same locality were green and beautiful. The cause of many lawns being browned directly dry weather sets in is due to the wretchedly poor condition of the soil. Lawns that are kept closely mown for years are certain to become exhausted if no attempt is made to improve the fertility of the ground. In many districts moss seems to luxuriate, and quickly covers the surface of the ground if not constantly stirred, and in such localities it generally takes possession of the lawns to the detriment of all the smaller and finer grasses, if it does not entirely eradicate them, which is certain to be the case if not destroyed. Impoverished lawns in this condition can be wonderfully improved in one season, and if the dressing is separated for a year or two a thorough renovation will be effected. If a rich top-dressing cannot be given lime is cheap enough in most localities, and this if freely applied will destroy moss, and grasses will spring up in its place. The lime if obtained fresh should be exposed to the atmosphere

until it falls to dust. For this purpose it is best placed in an open shed, or it may be reduced to powder by pouring as much water upon it as will just bring it to that condition.

To apply lime by itself is not one of the most enjoyable occupations, and the dust often renders trees and shrubs in close proximity unsightly for a time. Under these circumstances we always contrive to have a quantity of old potting soil that has been passed through a fine sieve under cover in readiness, and mix equal quantities of the two together. Failing this we use any ordinary fertile garden soil, and when well mixed it can be applied without creating any dust. This should be spread evenly, just covering the surface, out of the barrows as wheeled on. Select a dry day for the purpose, and when the whole has been spread it should be roughly brushed in with branches secured parallel to two poles. If this brushing is repeated a few times during dry weather, and then well rolled down, very little will be seen after the first good shower of rain. The lime for a time will certainly be visible, but by the time the grass begins to grow it will have been washed down out of sight. A good dressing of lime will destroy the moss, and before the season is over a marked improvement in the condition and appearance of the lawn will take place.

Our lawns are very subject to moss, and if they are not top-dressed about every third year it is certain to re-establish itself. We top-dress a portion annually, and by this means succeed in keeping the moss down and the lawns in presentable condition; in fact, only one of our lawns were browned last year. We have tried several mixtures, but find the following one most satisfactory. Old potting soil is reserved and passed through a fine sieve, and to every twenty barrowfuls is added two of lime, one of soot, and one of wood ashes; failing either of these, double the quantity of the soot or wood ashes is employed. To this about half a hundredweight of bone dust is added. If we have not sufficient potting soil, decayed leaf soil, old vegetable refuse of any description, or decayed manure, such as the refuse of Mushroom beds, are employed if they are in a condition to be passed quickly through the sieve. Sifting is not necessary as long as no very rough material is amongst that which it is intended to use. We sift the compost more for the sake of appearance than anything else, for when put on fine it is quickly worked down amongst the grass, and the lawn in a few weeks is presentable again. Three years ago we so treated a large lawn that was very poor, generally turned brown in summer, and was too full of moss. The second season Clover sprung up in abundance, and last season it spread through the whole of the lawn, and was beautiful and green all the season. Previous to the top-dressing I had not noticed any Clover in it. It may not be necessary to add lime for all soils, for the land may naturally contain sufficient, but for soils which contain only a very small per-centage, or next to none, lime will be found a valuable manure. This can be readily proved by giving lawns that are poor and full of moss a good dressing, for the improvement that takes place in one season is most marked, and its beneficial effects are not quickly exhausted.

Nitrate of soda is very good for strewing on lawns during showery weather in spring; it is very quick in its action but not very lasting. A good dressing will improve a lawn wonderfully in one season, and the amount of grass produced is astonishing compared with what was the case before its application. But the lawn is none the better for it the second season—such, however, has been my experience, and if I have observed rightly the lawns upon which it was used were left in a worse condition than before it was applied. I have tried several artificial manures recommended for lawns, and have always tested them by the side of bone dust. In several instances they have had the best of the bones for the first season, but in the end the bones have proved the best and most durable. We have some difficulty in making as much wood ashes as we require for various purposes, or we should use them more largely for dressing lawns, for we

have found wood ashes, being rich in potash, a very valuable fertiliser.

The best time undoubtedly to apply top-dressings to lawns is from the middle of February to the middle of March. The present is an excellent time. There is really no comparison in the appearance of a lawn that is top-dressed early in the season and one that is left until the spring has fairly advanced. When applied early it is well washed down to the roots of the plants, and directly they begin to grow their roots take possession of it, and its fertilising effects are visible from the first. But when lawns are top-dressed late in the season the material used often becomes dust dry, it remains amongst the grass in this condition for a long time, and the results that may be anticipated do not show themselves for some months—perhaps not till near the autumn. Much, however, in this matter depends upon the season, but where top dressing is required it should be delayed no later than the state of the weather will allow of it being done. To keep a lawn in good condition by periodical top-dressings does not entail much labour; in fact, most of the material employed can be prepared when it is impossible for men to do outside work, and when this has been done the work of spreading it on the lawn and brushing it in does not entail much labour. However, the better appearance of the lawn during summer more than compensates for any labour occasioned in carrying out this important work.—A NORTHERNER.

### ESTIMATES OF VEGETABLES.

**BRUSSELS SPROUTS.**—These as a main crop are not very remunerative, but taken as an intermediate crop contribute in no small degree to the annual proceeds. Perhaps the most important of the Brassicas from a marketing point of view are Brussels Sprouts, they being taken between the rows of Asbleaf or other kind of early Potatoes. The usual practice in field culture is to plant a row of Brussels Sprouts between every two rows of Potatoes, the latter being 20 inches apart, and the space between each pair of rows about 30 inches, which admits of them being lifted expeditiously, whilst the Brussels Sprouts make a sturdy growth, which is essential to the production of firm, close, heavy sprouts. We usually grow the imported, which gives firm compact knobs, and these are most esteemed, at least they bring the best prices from the salesman. Scrymger's Giant also gives large firm sprouts, and those are recommended for general purposes. For early use Veitch's Exhibition and The Aigburth are valuable, affording large sprouts, but they are not heavy, and do not fetch nearly as much money as the others. For late use Veitch's Paragon is very superior, the sprouts being close, heavy, and of medium size, and these bring the highest price in the market. Brussels Sprouts usually have the tops cut off in February and sent to market. That throws the vigour into the remaining sprouts, and the crop is then sooner cleared off the ground.

**CAULIFLOWER.**—Early London and Walcheren are grown principally for the first supply of heads in summer from sowings made at the close of August, and very excellent results are obtained from them if the crop can be got in early; and for main crop Walcheren must take first rank, if indeed it have an equal, for general purposes. The one that takes best in the market is Autumn Giant, its large close heads telling most effectively, and the best returns are realised, particularly in autumn and early winter. Where handlights are used Erfurt Mammoth is good as an early variety; but Veitch's Extra Early Dwarf Forcing and Snowball, the distinctness of which is questionable, though very valuable for private use are scarcely large enough for marketing, being placed at a disadvantage if they have to compete with large white heads of late Broccoli.

**BROCCOLI.**—Snow's Winter White takes precedence of all for winter use. Penzance Early White and Adams' Early White, the latter being much the hardier, afford an excellent succession, closely followed by Cooling's Matchless and Leamington. Veitch's Model is superb as a late variety, and gives fine heads on dwarf sturdy plants. Champion Late White is an admirable sort, whilst Lauder's Goshen is splendid in late April and early May, being very hardy, similar remarks applying to Ledsham's Latest of All, an excellent variety for marketing. Broccoli is planted generally in gardens and fields between the rows of Potatoes, and I find it best to insert the Broccoli between every alternate pair of rows of Potatoes, which allows the plants to get stronger, and, sturdiness meaning hardness, the advantage is

considerable; besides, the tops of the Potatoes can be turned away from the Broccoli plants into the space between the two rows of Potatoes if necessary, thereby keeping them sturdy, and the facilities for lifting the Potatoes is considerable, to say nothing of cleanliness afterwards.

**Sprouting Broccoli** is a paying crop, the best variety being **Early Purple Sprouting**, which, coming in when Brussels Sprouts are getting over, meets a ready sale, especially after such a season as the last, which was dry in summer, and that with the prolonged severity of the winter has told upon supplies to the advantage of the seller.

**BORECOLE OR KALE**.—This does not bring much to the grower, but being taken as a between crop, and one that may be planted later than autumn Cauliflowers or spring Broccoli, it occupies ground that might otherwise be vacant; and if there be a scarcity of greens in spring the crop may prove remunerative, at least is better than nothing. Tall and Dwarf Green Curled are the hardiest, but I find Read's New Hearting far ahead of all others in largeness of head and in resisting frost and wet, and stands longer than any other before running, bringing a higher price. Cottagers' Kale is useful, and both Buda and Asparagus affording sprouts in spring, they being very hardy, exceeding tender, and good flavoured.

**CABBAGES**.—The principal object is to get these into the market early, for which none surpass Ellam's Dwarf Early Spring. Larger varieties are represented by Denning's Early and Hill's Incomparable; Enfield Market and Battersea being best for the general crop. Drumhead is useful for spring sowing to afford Cabbages in autumn and winter, and so is Denning's, both remaining a long time fit for use and being hardy. Red Dutch is unsurpassed for pickling if care be taken in selecting plants for seed, choosing those that exhibit the highest colour, for to bring good returns the heads must be large, close or heavy, and deep coloured. Early Cabbage is usually taken after Onions, and the Cabbage is cleared in time for Peas, Runners, and where double cropping is practised late Celery between the rows of Peas.

**SAVOYS**.—In autumn and winter these are what Cabbages are in spring and early summer—the staple of green vegetables. For early cutting it is doubtful if there is any better than a carefully selected stock of Early Dwarf Elm, though I think Gilbert's Universal will, at least ought, to supplant it. Drumhead is the best for autumn and early winter use; but it cannot endure wet, and is soon spoiled by frost. To follow Drumhead Dwarf Green Curled is excellent, withstanding wet and frost well, but in loose soil is liable to form loose heads, therefore the soil should be firm; indeed, for all Brassicas in order to a sturdy growth, hardness of plant, and enlargement of the useful part or head. I do not know whether it is generally known or not that all the Brassicas succeed best sown where they are to remain, the ground being firm though in good heart, the seed drilled, and the plants afterwards thinned to the requisite distance. Planting, or rather transplanting, is only matter of convenience and utilisation of space. Chou de Burghley is useful to those requiring Cabbage in winter, being very hardy, withstanding wet well, the quality being excellent, but it does not find much favour at market. Similar remarks apply to Couve Tronchuda, it being esteemed in some private gardens, but is tender and is only useful in autumn. The thick midribs are used similar to Seakale.

**TURNIPS**.—Early Turnips are always in demand. The very best and earliest is Extra Early Milan Strapleaf. It is fine in shape and excellent in every respect; not the least of its merits is its small top, which admits of bunching readily. It comes into use a fortnight before any other, and keeps in condition some time. Next in order comes Early Strapleaf White Stone and Early Stone, or Six Weeks, both capital kinds for summer use. Veitch's Red Globe is superb for general crop and the best for late sowing, keeping well. Golden Ball, or Orange Jelly, is excellent for winter use, but does not find much favour with the cook, only being taken to when white-fleshed kinds cannot be had.

Turnips require firm soil. In loose rich soil they run too much to top, and the seed should be sown thinly or the plants thinned early. It may not be generally known that the best way to have Turnips late is to lift in autumn before the roots are much exposed to frost and lay them in on a north border, the Turnips being entirely covered with soil, which saves them from rot, as the tops are some protection, and from the vicissitudes of climate. In this way they keep until a very late period.—**UTILITARIAN.**

### SHRUBBY CALCEOLARIAS.

I CAN fully endorse Mr. Brotherston's practical remarks on this subject, and would recommend those of your readers who have not hitherto succeeded so well in the cultivation of this old-fashioned though indispensable bedding plant, to follow the method of procedure indicated at page

158, and which, if carried out in detail, will insure success. In addition to my own successful experience of the system advocated, I had the pleasure of inspecting the gardens and grounds at Tynningham early last September, on which occasion I was particularly struck with the healthy floriferous condition of the Calceolaria plants in the beautiful and well-kept flower garden opposite the south and west fronts of the mansion, and which, in connection with the well-arranged varieties of other flowering and foliage plants, made a very pretty floral picture, one which Mr. Brotherston might feel justly proud of.

The only Calceolaria grown here for bedding purposes is that excellent old variety *amplexicaulis*, which produces abundance of flowers of a beautiful soft yellow colour from the middle of July until nipped by the frost, and this we propagate in a cold frame in which the cuttings are inserted about 4 inches apart about the middle of October, a week earlier or later according to the weather, in the manner indicated by Mr. Brotherston. As all the beds in our Italian garden, except twenty-four beds devoted exclusively to carpet-bedding plants, are each planted with only one variety of plant, so as to have masses of distinct colours, ranging from scarlet to white, we plant it thinly in the beds to admit of the plants, which are of a straggling habit, being pegged down over the surface of the beds. Thus grown, the effect which *C. amplexicaulis* produces when contrasted with the masses of scarlet, pink, white, &c., is very telling.—H. W. WARD, *Salisbury.*

### HINTS ON ORCHID CULTURE.

(Continued from page 177.)

**ORCHIDS IN VINERIES**.—Some reference has already been made to the adaptability of vineries for many Orchids, but it deserves more particular attention. In ordinary early houses the Vines are started at a convenient time for starting the Orchids also. The temperature and moisture suitable for one is equally suitable for the other, and later on when the Grapes have been cut and the Vines are resting can be made the resting season of the Orchids. Many fine specimens have been grown in this way, and some of the most remarkable were those exhibited some years ago by Mr. L. Temple, then gardener to W. G. Joy, Esq., Headingley, Leeds. The success of the treatment may be judged from the following particulars of the principal plants:—*Cattleya crispa* *superba*, 4 feet in diameter, fifty blooms; *C. Harrisoniæ* *violacea*, 3 feet in diameter; *C. crispa*, 3 feet in diameter, thirty flowers; *Odontoglossum grande*, 2 feet in diameter, forty-one flowers; *Dendrobium nobile*, 4 feet in diameter, 400 blooms; *Miltonia Clowesi*, 3 feet in diameter, 100 blooms; *M. spectabilis*, 3 feet in diameter, forty-nine flowers; *Oncidium flexuosum*, 4 feet in diameter, forty spikes; *Phajus grandifolius*, 4 feet in diameter, thirty spikes; *Cypripedium insigne*, 3 feet in diameter, forty flowers; and *Dendrobium densiflorum*, forty-four spikes. Most of these were grown in tubs 2 feet 6 inches wide and 1 foot deep. These were exceptionally fine specimens, but all the following have been found to thrive with similar treatment:—*Anguloas* *Clowesi*, *Ruckeri*, *uniflora*; *Arpophyllum giganteum*; *Barkerias* *elegans*, *Lindleyana*, *Skinneri*, *spectabilis*; *Brassavola glauca*, *Brassia verrucosa*; *Cattleyas* *citrina*, *Harrisoniæ*, *crispa*, and others; *Cœlogyne cristata*; *Cymbidium eburneum*, *giganteum*, *Hookerianum*, *Mastersi*; *Cypripediums* *insigne*, *Schlimi*, *Sedeni*, *venustum*, and many others; *Dendrobiums* *nobile*, *densiflorum*, *thyrsiflorum*, *chrysanthum*, *Hilli*, *speciosum*, *Wardianum*, *Pierardi*, and others; *Epidendrums* *amabile*, *aromaticum*, *macrochilum*, *vitellinum*; *Lælias* *albida*, *acuminata*, *autumnalis*, *majalis*, *superbiens*; *Lycaste aromatica*, *cruenta*, *Skinneri*; *Masdevallias* *coccinea*, *Harryana*; *Maxillarias* *aromatica*, *grandiflora*, *Harrisoni*, *venusta*; *Odontoglossums* *Alexandrae*, *citrinum*, *cordatum*, *gloriosum*, *Lindleyanum*, *Pescatorei*, *nævium*; *Phalenopsis pulchellum*, *Uro-Skinneri*; *Oncidium* *bifidum*, *crispum*, *incavum*, *leucochilum*, *ornithorhynchum*, *serratum*; *Pleione humilis*, *lagenaria*, *maculata*, *Wallichiana*; *Trichopilia tortilis*; *Zyopetalums* *crinitum*, *Mackayi*, and *maxillare*. It may be remarked that the coolest position should be assigned to the *Masdevallias* and *Odontoglossums* at the forcing period of the year, and for this reason they are better in late vineries than in early ones, as the former are especially impatient of too much artificial heat.

**TEMPERATURE**.—Since Orchids are found in such widely varied districts it can be readily understood that with other conditions the temperatures to which they are exposed differ considerably. In cultivation, however, we are compelled to group the plants as nearly as possible according to their respective requirements as regards heat. Nurserymen and wealthy amateurs who have extensive collections commonly devote houses to each of the larger genera, structures being appropriated to *Cattleyas*, *Lælias*, *Dendrobiums*, *Cypripediums*, *Phalenopses*, *Vandas*, *Odontoglossums*, *Masdevallias*, &c.; but in smaller establishments it is seldom that more than three houses can be used for Orchids alone; and all that need the protection of glass can be readily grown in those by regulating the temperature. Thus the warmest house (day temperature of the year 65° to 80°) would contain the Orchids from the tropical regions of the Old World, especially the East Indies, the Malayan Archipelago, and adjoining

countries on the main land. An intermediate house (day temperature of the year 60° to 75°) would be used for the tropical Orchids of America, comprising the Cattleyas, Lælias, and other plants from Brazil and the lower parts of Mexico. The third house (day temperature of the year 50° to 65°) would answer for most of the Odontoglossums and Masdevallias, with other plants from high regions in tropical countries. All indoor Orchids can be satisfactorily grouped in these three divisions, and in the following notes they will be referred to as the warm house, intermediate house, and cool house. It should be observed that in general practice there has been a great reduction in the temperatures for Orchids, and some very experienced growers, like Dr. H. Paterson of Bridge of Allan, rely exclusively upon sun heat for the higher summer temperatures, and at that season frequently have no artificial heat. There can be no doubt that highly heated houses during the winter when we are compelled to rest the majority of our Orchids is exceedingly injurious, weakening them and rendering them precocious in flowering, and much more liable to the attacks of insects. If strong growth is made and well ripened under plentiful sun heat and free ventilation Orchids will endure a much lower temperature than is usually supposed, and will be far more satisfactory than when roasted, as they were in the early stages of Orchid culture. As a general guide to the temperature of the year for Orchid houses the following table, which was included in the paper read by Mr. James O'Brien before the Orchid Conference in 1885, is very useful:—

TABLE OF TEMPERATURES FOR ORCHID HOUSES.

Months.	Warm House. East Indian.		Cattleya, or Inter- mediate House.		Cool, or Odonto- glossum House.	
	Day Degrees.	Night Degrees.	Day Degrees.	Night Degrees.	Day Degrees.	Night Degrees.
January .....	65-70	60	60-65	55	50-55	45
February .....	65-70	60	60-65	55	50-55	45
March .....	65-70	60	60-65	55	55-60	50

December .....	65-70	60	60-65	55	50-55	45

Amateurs are often puzzled as to the quantity of piping to be used in a house to maintain a particular temperature; and though these matters are best entrusted to horticultural builders, who will give the consideration to the position, exposure, and other circumstances bearing on the point, yet a few hints may be useful as a guide. Many formulæ are given for the purpose of calculating the approximate number of feet of piping necessary, but they are all somewhat perplexing and occasionally misleading. The following, based on a table by Mr. F. H. Fawkes, has the merit of simplicity, and it is, moreover, as nearly correct as any calculation of the kind can be. The length of 4-inch piping named is that needed for each 1000 cubic feet of internal atmospheric contents, and the temperatures, as elsewhere in these notes, are given in degrees Fahrenheit.

Warmest house, 65° to 80°. Lean-to houses, 55 ft. to 65 ft. Spans, 60 ft. to 70 feet.

Intermediate house, 60° to 75°. Lean-to houses, 50 ft. to 60 ft. Spans, 55 ft. to 65 ft.

Cool house, 50° to 65°. Lean-to houses, 40 ft. to 50 ft. Spans, 45 ft. to 55 ft.

These figures practically correspond with what is usually recommended for span-roof houses of good size—namely, warm house, four rows of pipes in each side; intermediate house, three rows; and cool house, two rows, and from them an idea can be gained as to what extent of piping is needed, but it is always advisable to have too much than too little, as is proved in houses of all kinds, whether devoted to plants or fruits. The greater the radiating surface the more regular the temperature, and the less injurious it is to the plants in severe weather when it may be necessary to keep the fires going briskly.

It may be observed that if a few particulars are known respecting the habitat of newly introduced Orchids it is not difficult to provide for their requirements. The first point is to ascertain the country and latitude, then the altitude, and finally any other circumstances, such as whether the position is exposed or shaded, and in the case of terrestrial Orchids the character of the soil in which they are growing. The rule usually given for calculating the depression of temperature in ascending mountains is to allow a fall of 1° Fahr. for every 300 to 350 feet of altitude, but the depression is more rapid in the higher regions. Thus in the tropics, where the temperature at the ground level might be 80°, at an elevation of 6 to 7000 feet would be estimated to be 55° to 60°. This is, however, necessarily influenced to a great

extent by the position of the land, whether sloping towards the sun or not, also whether the mountains are near the sea or inland; but an approximate idea may be gained of what the plants need.

#### CULTURAL MATERIALS.

Good results in plant culture are largely dependent upon the soil employed for them, and too little attention is often paid to the subject. For Orchids it is particularly important, and a few notes on the principal materials necessary may be useful.

**PEAT.**—This is a well-known substance used extensively for hard-wooded plants, Heaths, &c.; and for the majority of Orchids it is indispensable. It varies greatly in its character, depending chiefly upon the nature of the soil where it is obtained and the roots of which it is composed. In some places it consists mainly of the roots of grasses and a black soil derived from the decomposition of vegetation, and is then termed bog peat; in others it chiefly comprises wild Heath roots and finer grasses, and is found in higher districts, a third kind being mainly formed of Fern roots and rhizomes, both the last named containing a varying proportion of light brownish soil from the farther decomposition of the roots, &c. These are the principal kinds, but there are many intermediate grades. The bog peat, which also generally contains a proportion of sand, is most suitable for Heaths and similar plants; the second kind is used for Ferns, and the third is the best for Orchids. For these plants it must abound in fibre, and the smaller particles should be shaken out before it is used, when it can be broken up into pieces of various sizes according to the plants for which it is to be employed, but never very small. If a quantity is procured at one time it must be stacked where it will not be exposed to the wet, and yet not in a hot position where it will become too much dried. When ordering peat intending purchasers should state that it is required for Orchids, and the dealers will then know what to supply.

**SPHAGNUM.**—The moss used for Orchids consists mainly of *Sphagnum obtusifolium*, but *S. squarrosum*, *S. acutifolium* and *cuspidatum*, with others that have been considered as varieties of one species, are also abundant in some districts. These are termed bog mosses, and are found in low moist places frequently partly submerged, and are abundant in most parts of Britain. The sphagnum serves as a retainer of moisture, and by its decay furnishes something for the support of the plant's grown in it. When received it should be spread out on a bench or floor and carefully picked and selected, removing all the weeds, leaves, grasses, or foreign substances, and divide it into three qualities. The first should consist of the fresh-growing points of the shoots, which must be preserved for surfacing; the next in freshness will be set aside for chopping up and mixing with peat for potting; and the third, comprising all the roughest and most decayed portions, being employed for covering the drainage in the pots before the principal soil is placed in. It should all be kept in a damp warm position, especially the first named, to induce growth, which soon takes place under favourable circumstances, assuming a bright green colour. The chopped sphagnum is sometimes scalded with hot water to destroy insects, and in any case these must be looked after very closely or they will do much mischief afterwards, when they cannot be so readily found. A substance termed Trepho, consisting of compressed sphagnum, is prepared and sold by Mr. B. Field, 170, Old Kent Road, and has been recommended by several Orchid growers for blocks or for potting purposes. The sphagnum is placed under hydraulic pressure, and thus formed into compact firm blocks that can be cut to any size required, which, as might be imagined from the nature of the substance, are very retentive of moisture. It is employed in this way as blocks to grow Orchids upon and for breaking up as a substitute for or an addition to peat. It is well worth a trial, and the fact that it is being employed by some nurserymen is a sufficient proof of its merit.

**LOAM, CHARCOAL, AND POTSHERDS.**—For exotic Orchids loam is not much used except for *Calanthes*, a few *Cypripediums*, or other strong-growing species; but whenever employed it should be of a light fibrous character, heavy and clayey loam being especially avoided, and that of a very sandy nature is also unsuitable. It must be stacked as for other plants and used in an intermediate state of moisture. Charcoal is an important material for mixing with compost for many Orchids, and some, like the *Phalænopses* and others of that character, can be grown in that and potsherds alone. The latter must be thoroughly cleansed and sorted in different sizes, using the largest for the lower drainage in pots and for baskets.

**MANURES.**—Though ordinary manures have been long used for strong-growing Orchids of the *Calanthe*, *Cypripedium* *insigne*, and *Dendrobium nobile* types, they have not come into general use for other Orchids, and it is quite evident that although some of the character named may be benefited by stimulants, these must be employed very sparingly and with great judgment for the majority. It is true that many tropical Orchids grow where there is naturally a luxuriant vegetation, and the gases arising from the rapid decomposi-

tion may be supposed to be beneficial; also that bird guano deposited upon the stems and branches of trees may afford some support of this kind. Under artificial conditions it is, however, necessary to be extremely cautious or much injury will result, and beginners had better abstain from dangerous experiments until they gain more knowledge of Orchid culture. Some experienced cultivators have, however, proved that manures can be employed with advantage, and several have been recommended for the purpose. Cow manure in an old and partially exhausted condition is used for mixing with the soil for strong terrestrial Orchids, chiefly for those needing loam, and which will be afterwards enumerated. Horse, sheep manure, and soot are similarly used, but the most elaborate trials appear to have been made with Jensen's fish guano, Mr. A. Borwick of Higham Hill, Walthamstow, having tried it generally on a miscellaneous collection of Orchids with evident advantage to the majority, especially *Cymbidiums*, *Lycastes*, and *Coelogynes*, which have made very strong growths. This was used at the rate of a 48-potful to a barrowload of peat or other soil; but it is safer to use a smaller quantity, and in any case this or any other manure should be thoroughly mixed with the compost. The manures named are also used as liquids diluted with water, but these must always be very weak—scarcely tinged; or in the case of the fish potash  $\frac{1}{4}$  oz. to a gallon is ample, and less is advisable. As liquids, and for sprinkling upon the stages or floors of houses, some persons have tried nitrate of soda, sulphate of ammonia, and carbonate of ammonia, which are dissolved in water and then sprinkled about. Sometimes pieces of the carbonate are placed in jars in the pipes and allowed to remain there constantly, thus giving off a supply of ammonia. Experiments of this kind have been found

Fig. 31.

Fig. 32.

Fig. 33.

to improve the colour of the foliage wonderfully; but when given to the plants in a comparatively strong state they either make a vigorous growth and become exhausted and turn yellow, or their roots are at once killed. At The Grange, Wallington, the residence of A. H. Smee, Esq., where so many interesting experiments have been tried, Clay's Fertiliser has been employed for many Orchids, applied as a top-dressing for the strongest, or about a spoonful is placed in a gallon of water, and the liquid thus formed is given to the majority of terrestrial Orchids. A very strong specimen of *Cyrtopodium Saintlegerianum*, which had been thus treated has been exhibited and certificated at South Kensington.

#### CULTURAL UTENSILS.

**POTS AND PANS.**—Large numbers of Orchids are now grown in pots and pans, more so, perhaps, than formerly, when baskets, rafts, and blocks were almost exclusively used for epiphytal species. They are obtained in a great variety of sizes and shapes; some very artistic, such as Mr. Matthews occasionally exhibits, and others of plainer design, but equally useful. Those with perforated sides are preferred by some, and they have the advantage of affording a quick drainage, which is necessary if deep pots are used. Shallow pots or deep pans for large specimens are, however, being more generally employed, and of late small pans, 3 inches deep and 4 to 6 inches in diameter, have become popular for many Orchids, and it is astonishing what pretty plants can be grown in them, *Odontoglossums* of the *Cervantesi* and *Rossi* character, *Sophranitis*, and other small Orchids doing well, while some of the *Dendrobiums* succeed admirably in the same way. All, in fact, that do not need much root space. Where insects are troublesome it is a common practice to invert a pot in a saucer of water and place the other on this; but a simpler way of accomplishing the same object is afforded by the Orchid pan employed at Downside, Leatherhead, which was prepared from a design by the gardener, Mr. Woolford. It consists of an ordinary saucer, in the centre of which arises a little pillar expanded at the top into a flattened plate, upon which the pot is placed. The saucer being then filled with water, no insects can pass from the stage to the plant.

**BASKETS AND BLOCKS.**—Baskets suitable for Orchids are readily

constructed, but they are now so cheap that it is much better to purchase them from some of the dealers, from whom they can be obtained of any size desired and of several forms. They are mostly made of teak, and are very durable, though constantly exposed to moisture. The principal forms are shown in the accompanying cuts, which represent some of those made by Mr. Sidney Williams, 21, Farringdon Road. The ordinary square basket is formed with the bars extended at the end, as in fig. 31, or with the ends flush, and it is immaterial which is employed; they are also made with four wires for suspending them by, and with two, but the former is generally preferred. Fig. 32 represents a boat basket, a convenient form for some Orchids, and fig. 33 is a cylinder, employed in many establishments for *Phalænopsis* and similar kinds. Mr. Bonny, Hackney Downs, also constructs very useful baskets in which the wires are removeable, so that different lengths can be employed as desired, and cane is used between the bars instead of lead. For blocks almost any wood is suitable that is not so soft that it readily decays, or of so hard and close a texture that the roots cannot obtain a hold upon it; but teak slabs are also frequently used as blocks, rafts formed of parallel bars answering the same purpose. A soft freestone has been used as blocks for epiphytal Orchids with good results, and porous earthenware pots, filled with water inside and the plants secured to the outer surface, have been found similarly suitable for many species. The use of compressed sphagnum for this purpose has been already noticed.

Of miscellaneous utensils the most important, in addition to the ordinary watering cans with fine and coarse roses, and syringe with nozzle and rose, will be a little metal tank on wheels for dipping baskets, blocks, &c., where the collection is large, as it can be taken round the house and the work quickly performed. For a small collection a pail will suffice.—AN AMATEUR.

(To be continued.)

#### A FEW NOTES ON CLUBBING.

OCCASIONAL notices appear in your valuable Journal in reference to this disease, and where it is experienced in so bad a way as here, no one would be surprised at every attempt being made to overcome it. I believe, however, that but few culturists experience it really bad. I have been employed in gardens where it hardly ever occurred, and it never gave any anxiety. Cauliflowers were frequently destroyed by maggots, but this is very different, and not so bad when in its worst form as clubbing. Where I write clubbing is so certain that with the exception of curled greens and Cabbage, all the other kinds—Cauliflowers, Sprouts, Savoy, and Broccoli—are but risky crops to grow on account of this pest. The soil here is a light friable loam on a gravel subsoil. In my first year's experience of it I thought I had a fairly good supply of winter vegetables coming on, but before the summer was nearly over, on some hot days I scarcely understood what was wrong with the stretch of Brassicas, as all the leaves were quite flat, but after further inspection it soon was proved to be clubbing, worse than ever I had seen it before. After this I made many inquiries on this subject to see what could be done to cure it. In one case I was told that the ground was exhausted, and if it was trenched, bringing up fresh soil, that would cure it. This was done, but it had not the desired effect. Next, I think, I tried liming, digging it in in the winter time after it was spread on the surface in quantity like a fair ordinary manuring. After this the clubbing was not gone. Again, or next year, at planting time I had a large heap made up of leaf mould, soot, old potting soil, and such material as could be collected, and under each row of plants I had some of this put to the roots. After this the result was the best that I have yet had. I have noticed that some ground seems to favour it more than others, and I have pulled plant after plant in the autumn with the clubbing so large that the roots might be said to be as large as both hands shut together, or the size of a cocoa-nut, only rough in form. Some years I have bought in all, or nearly all, of the plants from ground where they did not club, and no doubt this was a little help, as it was hopeless to plant those of our own raising when they were beginning to club in the seed bed. We have been tolerably successful with early Cauliflowers, but these are usually plants out of pots, and if I want to make the most of them I resort to the plan of placing fresh soil to the roots, such as old potting soil. It would be a great advantage to us if we knew a simple and effectual cure.—R. M., Cheshire.

#### LIME FOR VINE BORDERS.

##### ANALYSIS OF SOIL.

IF "A. L. G." reads my remarks on page 104 again, he will see that no personalities were intended. He thinks that the information he gives is correct. Does he mean the method by which he tests whether soil contains lime or not, or the extracts quoted from Warrington's "Chemistry of the Farm?" The point has not been disputed, but the accuracy of the latter he has failed to demonstrate. On the contrary, he now advocates the use of lime, but the quantity quoted for land similar to what I described would be of very little service. I have tested this small application system, but it neither prevents clubbing nor adds materially to the productiveness of the land. A liberal dressing, such as "Thinker" and

myself have recommended, would change the nature of the soil, prevent clubbing, and add to the fertility of the land for several years without a further application. "A. L. G." condemns my method of applying lime, but what really is the difference between his system and my own? Practically there is none. He writes "pricked in," and I say Dig it in. Digging the ground by both is advised, and if manure is to be used it should be dug in before the lime is applied.

I have learned by practice that 12 per cent. of lime reduced to powder is not too much to incorporate with limeless soil for Vines. I am willing to grant that the fibre of the loam may be decomposed somewhat more quickly than would be the case if not mixed with the soil; but had not this better be done than the Vines grown for a number of years without sufficient lime in the soil in such a condition that they could take it up and utilise it for their support? Plants only take up by their roots in a liquid state what food they require—that is, water, other substances being dissolved in it. I do not here allude to what they take from the atmosphere by their branches and leaves. This being the case, how long would it be before the whole or nearly whole bones advised were sufficiently dissolved to supply the requisite quantity of lime to the Vines? I have made Vine borders on this principle, not with whole bones, but inch and half-inch sizes with the dust left in. This produced wood strong enough, but it was always pithy—never had that firmness desirable in well ripened canes. When lime was applied, as recommended in my first and second article on this subject, it changed this state of things, and the process has been continued because it has proved advantageous. I think it is of very little moment whether bones are used fresh or not, for the loam selected for Vine borders is generally, or should be, rich in nitrogenous food—in fact, too rich, and failure is not unfrequently the result. Vine borders made but a few years ago with flesh and bones freely incorporated were, by all accounts, to revolutionise Vine-growing; but the reverse proved the case, for the borders were poisoned and the Vines proved a failure.

On page 153 "A. L. G." writes—"If slacked lime is applied it would be better as a top-dressing, but not in the way Mr. Bardney advises;" and further it is stated—"It would be better to give the lime first and wash it in before applying the compost." On page 37 I wrote—"The lime was mixed with water in a tank outside the house, and then poured upon the border and washed in with tepid water. In autumn several barrowfuls were worked into the border." How does your correspondent suppose it was worked into the border but into the surface, and what would he call this but a top-dressing? Again, at the close of my first article, page 38, I write—"In cases where borders have been made with soil from a sandstone formation, and the Grapes are not colouring well, or the Vines not satisfactory in other respects, and the quantity of lime given them has been small, they might be materially improved by a liberal dressing for a season or two, the dressing of manure being dispensed with for that time." It is needless for me to write further on this head.

The small quantity of ammonia that might be driven off by incorporating lime with the compost is not worth naming. The whole ingredients of the compost when placed upon the border become part of it, and are not removed in autumn and winter. I do not believe in putting it on to take it off again, but what is given is taken full possession of annually by the roots. Mushroom-bed refuse, or the manure from hotbeds that may be used, is placed upon the border as a mulching, so as to keep the compost beneath moist. This is removed annually, but not that incorporated with the loam and lime, and which adds humus to the border. If "A. L. G." puts manure on Vine borders annually and takes it all off again I am afraid the roots of his Vines are not very near the surface, or if so he must destroy a great quantity in its removal. Good agricultural soils are supposed to contain from 3 to 10 per cent. of humus, and a rich garden at least 25 per cent. This is three times the quantity, and if a Vine border is not as rich in humus as the last then it ought to be. I do not know what is the condition of "A. L. G.'s" border, but mine are rich in humus, and so are the majority of others from which good Grapes are cut.—WM. BARDNEY.

"T. S." writes: "Will Mr. Bardney kindly say if he measures his lime fresh from the kiln or after slacking? I presume it is in the first-named state, but as slacked lime occupies more space than stone, I should like to be clear on the point."

Replying to this question our correspondent sends the following note:—

"The lime used for the kitchen garden was measured as received and before slacking, but for Vine borders after being reduced to powder. We generally keep a quantity of lime in an open shed during the winter for mixing in the compost for top-dressing and working into fruit tree borders. This frequently absorbs sufficient moisture to cause it to fall without having to apply any, except perhaps to any lumps in the interior of the heap."

#### POTATOES FOR EXHIBITION.

I WAS much interested in Mr. Iggulden's remarks under this heading, but I cannot understand why Mr. Howard should grow Edgcott Purple for the last time in 1885 "owing to the quality being second rate or worse;" and yet farther on Mr. Howard selects it with eleven others as "good for both table and show." Surely there is a mistake here. I see Mr. Bresee is retained. With me, on my very light soil, it is a handsome and prolific Potato, but I can only call the quality second rate; and it frequently has streaks of pink right through, which does not improve its

appearance on the table. White Elephant has been good with me the last two years, but before it was inclined to be waxy.

I miss two Potatoes from Mr. Howard's list which I find exceedingly good in quality and appearance, Sharpe's Victor and Matchless. They are both great favourites of mine, and I cannot find a fault with them. Perhaps they may be of inferior quality elsewhere, for it really is very striking how Potatoes differ according to locality.

We have now had Mr. Marriott on Peas, Mr. Iggulden on Potatoes and Melons, and Mr. Abbey on Melons. Is it asking too much to request some of your able contributors to give us their opinions and experience in Cucumber culture, or Beans, or Onions? So far I find Purley Park Hero Cucumber, Ne Plus Ultra and Negro Mammoth Dwarf Beans, and a selection of White Spanish Onion the best to grow. Can I do better?—H. S. EASTY.

#### TUBEROUS BEGONIAS.

THESE plants have been much improved of late years, and as a consequence they have become most deservedly popular. Yet they are by no means generally so well known as might have been reasonably expected. There are few amateur or professional gardeners who have not made an attempt to cultivate Tuberous Begonias, but only a small per-centage succeed as they hoped. The true cause of so many failures is an over-anxiety, this leading to coddling and other mistaken practices, especially at the commencement of the growing season, which ultimately reduces the plants to a sickly appearance, and for which there is no cure during that season at least. There is really nothing to prevent all classes growing these beautiful Begonias, as they are essentially everybody's flowers, being equally as well adapted for window as house culture.

My first serious attempt at the cultivation of Tuberous Begonias was made about five years ago with a strain kindly sent from Drumlanrig by Mr. D. Thomson, and although the sorts obtained are not so showy and beautiful as those raised from seed since supplied by Messrs. J. Laing & Co. and Messrs. Sutton & Sons, they possess much stronger constitution, the tubers now being large enough to produce numerous strong growths. They are kept for conservatory decoration, and are useful for back rows. Home-saved seed invariably germinates most surely, but I am disposed to think the purchased seed may either be mixed—that is to say, is of two or more season's growth, or the strains are choicer and therefore possessing less vitality. It is a well-known characteristic of extra choice sorts to be of delicate growth. Instead of grumbling as many do at the smallness of a packet of seed, and it must be admitted packets of choice Begonia seed are very small indeed, the novice and even the experienced ought to be thankful that one cause of disappointment may by this means be averted. It is in this way. We sow all the seed, and if fortunate the greater part germinate, but as all are not wanted, there being more than can be properly grown, only the strongest are pricked off and the best as it were left in the seed pan to perish, simply owing to their being passed over in favour of their stronger yet inferior brethren. When we have only comparatively few seeds we of necessity cultivate every plant obtained from the sowing, and thereby secure one or several valuable sorts that are worth much more than the seed cost, and the remainder perhaps will be also considered worth keeping for a time. I have been supplied with tubers of several good double varieties, but from one packet of seed we have secured several very fine sorts, including two valuable whites, really superior to the named sorts. I mention this because so many complain to me of their "bad luck" with seed of double sorts, and for which they have most frequently themselves to blame. We have also raised several very good singles from seed, but as a rule they are not equal to the choice named sorts, of which tubers are distributed in a dry state.

I consider the first week in February a good time to sow the seeds, as at this time the sun has not gained much power; whereas if the operation is delayed till late in the spring, a great difficulty is experienced in keeping the seed pans uniformly moist without also either disturbing the minute seeds or the delicate seedlings. A mild hotbed, in preference to any drier heat, formed in a forcing house, is the most favourable position for raising the seedlings, but many, with a little extra trouble, are also very successful with Cucumber or Melon frames only. Either pans or well-drained pots are suitable, these being prepared for the seeds by having the drainage covered with any rough material, on this being placed sufficient fine peaty soil, or failing this sifted loam and leaf soil in equal proportions, adding sand freely to fill them up to the rim. This should be made firm and quite smooth and level, and then either lightly soaked in a tank or tub of warm water, or be properly moistened through a fine-rose watering pot. After the water is drained out of the pots or pans, as the case may be, the seed may be sown, this

being done very carefully and evenly from the tiny paper it is folded in. It must on no account be covered with soil, but a little fine dry silver sand may be dusted over, though no more of this than will just whiten the surface. Some prefer to sow on the top of a rather heavy surfacing of sand, but I have found when this is done that the seedlings are very slow in gaining a root-hold, many being lost after germinating. The pots or pans should be plunged into the hotbed and be covered closely with a square of glass, a little of the plunging material being distributed over the latter. The soil must be kept uniformly moist, but the less watering there is needed the better, as the seeds or even the seedlings are easily dislodged and ruined. We never venture to water our very fine seeds or seedlings, as sprinklings through a very fine-rose watering pot besides being risky are sometimes deceptive in their effect. The best plan is to partly immerse the pot or pan into a bucket or tank of tepid water, allowing the moisture to gradually work upwards, then after withdrawal if the drainage is good the water soon leaves them and without unduly saturating the soil. I must, however, warn some of my younger readers to whose tender mercies a packet of Begonia seeds may be consigned, that partial immersion is very different to submersion, as if the latter plan of moistening the soil is adopted there is every prospect of some unoffending seedsman being condemned for supplying bad seeds, and which perhaps were simply washed out of the pots.

Directly the seedlings are discernible the shading should be removed from the glass, returning a portion of it only whenever the sun is shining brightly. In the course of about three days the glass may be propped up, but not removed till such times as the seedlings may be strong enough to stand a little rough usage, or say part of the contents of a syringe which many are rather fond of throwing about where least needed. The seedlings are best kept on the hotbed, as there is little danger of their being drawn, and dry hot shelves are not suitable for Begonias in any stage of growth. When the most forward of them are large enough to handle they should be pricked out about 2 inches apart in pans of fine soil, composed of equal parts loam and peat or loam and good leaf soil, the latter preferably, adding silver sand freely. This ought to be warmed prior to being used, and if very dry be moistened with tepid water. The strongest of the seedlings may then be transferred to the pans with the aid of a label without disturbing those that are not large enough to remove, the holes made being filled up if necessary with a little fine soil or sand. After being watered the seedlings pricked out should be stood with the original seed pan and shaded when necessary. Directly they touch each other they should be transferred, with little balls of soil and roots, to ordinary Pelargonium boxes, these being previously drained and filled with rather fine compost similar to that just recommended, disposing them about 4 inches apart each way, still be kept growing on the hotbed. We find that they grow much more freely in these boxes than they do when potted, and it is just at this intermediate stage when so many seedlings come to a standstill. By the time they are become established in their fresh quarters they will need less heat and should be gradually inured to a cooler house or frame, the same treatment being given to those that were necessarily left in the seed pan for a few days or weeks longer.

The next point to be decided is whether these seedlings shall for a few weeks, or rather months, be grown in the open air or be hurried into flower under glass. This to a certain extent ought to depend upon circumstances. Those who want an early display may pot their seedlings as soon as they touch each other, 5-inch pots being a good size, and a suitable compost consists of two parts of turfy loam to one of leaf soil, a little fine decayed manure and silver or gritty sand being mixed with it. Those newly potted plants may be kept rather close, but not in a high temperature, for a few days, and directly they are recovered from the slight check they may be removed to a greenhouse and encouraged to flower as long as they will. A fairly light position should be assigned them. They ought not to be pinched back at any time, are not benefited by syringings, but ought never to suffer by want of water, and when the pots are full of roots they will be greatly assisted by frequent supplies of weak liquid manure. In this manner it is a comparatively easy matter to secure strong branching plants by the autumn; but if strong tubers are wanted for the following season to replace, it may be, the stock of older and inferior sorts, it will be found most advantageous to plant them out during the summer in temporary frames constructed at the back of a south wall. About 6 inches of good light soil (we use decayed leaf soil freely) is ample, and in this they may be transplanted from the boxes, disposing them about 6 inches apart each way. They may be covered with frames for a few days, but would succeed without them, and with little further trouble soon grow to a good size and flower freely. They

can be readily potted when in full bloom, a little shade being given for a few days, and for house decoration during September and October we have found plants thus grown of great service. Any not worth farther cultivation are weeded out, and the remainder not potted up are lifted after being damaged by frost and stored thickly in Pelargonium boxes, the soil immediately surrounding the tubers being sufficient to keep them plump and sound, all that is necessary being to protect them from severe frosts. I have taken more space than anticipated in describing our method of raising these Begonias, and must therefore postpone my remarks on propagating by cuttings as well as the starting and subsequent treatment of dry tubers, the latter being best kept dormant for some time longer.—W. JGGULDEN.

#### SPARROWS DESTROYING GOOSEBERRY AND CURRANT BUDS.

UNTIL within the last three years I have not had any experience of sparrows destroying fruit buds. I have defended them from attack in the columns of this Journal on more than one occasion, and though I now admit that they do eat fruit buds I am not prepared to wage a war of extermination against them. Last winter marked my first experience with sparrows eating Gooseberry and Currant buds. Sprinkling the bushes with petroleum in mixture with water at the rate of a quarter of a pint per 3 gallons, 2 ozs. softsoap per gallon having previously been dissolved in the water, was sufficient to keep them away; but this winter they commenced on the Currants in November, the blue titmouse being their forerunner on the bushes, which I attributed to the birds' search for aphides. The blue titmouse certainly did not destroy any buds, or only where the buds were so clustered on the spurs that in getting at the aphides secreted there some few of the buds had been disturbed and were left on the ground entire. I thought the sparrows had come to assist in the good work, but I found they took the buds altogether. The petroleum remedy was tried, but though it deterred them at first the sparrows were at the bushes again directly after the first rain following the petroleum dressing. It was of very little use, and as destroying the birds was forbidden—and I think rightly—I was driven to the expedient of running black thread in wide mesh-like order over the bushes. This answered perfectly.

I have some rows of winter Spinach between rows of the bushes, and the leaves were eaten by the sparrows, even the hearts being pecked out. A single row of black thread directly over the Spinach, and quite 6 inches above ground, is sufficient to keep them off. I have long been accustomed to run lines of black thread to keep them from eating Peas after they appear above ground and until fit to stake; but last year I had to run thread a considerable height up the Pea-sticks to keep the sparrows from eating the Pea leaves and tender shoots off. They are very fond of Lettuces, eating that standing for spring and early summer use with great avidity; also the first leaves of Radishes, pulling up the plants, and seem to take especial delight in drawing Onions as they appear above ground, and cutting off Beet plants. In hard weather they will take to the leaves of Brassicas, but like something more tender if it can be had. Sparrows pluck off the pips of Primroses, Polyanthus, and Auriculas, and tear the bloom of Crocuses, particularly the yellow ones, into shreds. If they have their own way they do considerable mischief, but take the precaution to have black thread in store, keep a sharp look out, and then the sparrow is useful. It devours myriads of aphides; it clears foliage of an incalculable quantity of small caterpillars.—G. ABBEY.

At a general meeting of the ROYAL HORTICULTURAL SOCIETY, held March 9th, Geo. F. Wilson, Esq., F.R.S., in the chair, the following candidates were unanimously elected Fellows—viz, Miss Beatrice G. Astley, H. R. Chaston, Sir Francis Cook, Bart., Robert Delf, Mrs. Sewell, Walter Watts.

— GRAND NATIONAL DAHLIA SHOW, 1886.—The arrangements in connection with the Grand National Show of Dahlias to be held on September 3rd and 4th at the Crystal Palace have now been completed. The prize schedule has been printed and circulated amongst the former subscribers and exhibitors; the same well-known and trusty florists have been selected to award the prizes, and the same Executive Committee has been appointed as a substantial aid to the Honorary Secretary. In regard to its finances, the Show cannot be thoroughly successful unless liberally supported by the growers and admirers of the Dahlia, who will therefore, we trust, keep the officials busily occupied in sending out receipts for their donations. Those also who believe in the beneficial influence of

flower shows may well lend a helping hand. Contributions should be sent to the Honorary Secretary and Treasurer, Mr. Thomas Moore, Botanic Garden, Chelsea, London, S.W., who will gladly acknowledge them. We may add to the foregoing that the second of the Dahlia competitions for the possession of the TURNER MEMORIAL PRIZE CUP will take place at the Crystal Palace on the occasion of this Show, and will greatly increase the interest with which it can be watched by those who are admirers of this noble autumn flower.

— RELATIVE to the FROST that has prevailed during the past week, Mr. N. H. Pownall states that the thermometer registered 10° on Sunday night last, or 22° of frost in Lenton Gardens, Nottingham; on the same morning the reading at Old Warden, Bedfordshire, by Mr. Allis was 18°, or 14° of frost. A Wakefield correspondent writes: "The weather in this neighbourhood seems to get more severe. The thermometer registered 24° below freezing—viz., 8° last night (8th inst.), and the ground has been covered with about 7 or 8 inches of snow, which has every appearance of remaining some time. This is an anxious time for gardeners." From Alderminster Lodge, Stratford-on-Avon, we have received the following:—"We are having very severe weather at night, with bright sunshine in daytime. The last three nights I have registered on a sheltered warm south wall 16°, 19°, and 18° of frost, while in the open on the north side 23°, 25°, and 24° have been registered. The winter and spring Beans will, I fear, be greatly injured." In the vicinity of London sharp frosts have prevailed and keen winds, but no snow, and the last few days were sunny.

— WE are informed that MESSRS. SUTTON & SONS, Reading, intend offering upwards of £16 in six prizes for collections of vegetables at the Provincial Show of the Royal Horticultural Society at Liverpool, also three prizes for Melons, particulars of which will no doubt be issued in the schedule of the Exhibition.

— MR. H. S. EASTY writes: "In answer to 'A. M.'s' inquiry respecting the SELECTION AND SUCCESSION OF PEAS, I think he will find the following of high quality and prolific bearers:—Gem of the Season (Daniels), William I., Dr. Hogg, for earliest; Champion of England Duke of Albany, and Evolution, for midseason; Ne Plus Ultra, Veitch's Perfection, Veitch's Sturdy, and Laxton's Omega, for latest. Dr. Hogg is nearly if not quite the sweetest Pea grown, and no Pea excels Ne Plus Ultra. 'A. M.' was really answered, and extremely well answered, on page 183, 'Peas for Use' ('B. L. E.'). Only three varieties are mentioned there in place of my ten."

— WE understand that the well-known botanist, DR. E. REGEL, who has been director of the St. Petersburg Botanic Gardens for a number of years, has resigned the appointment, and has been succeeded by Dr. Engler.

— THE GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY announce their Spring Show this year for March 24th, the Autumn Show taking place on September 8th in the St. Andrew's Hall. The schedule is of the usual character, a large number of classes being provided, and the prizes ranging from £4 to 3s.

— MESSRS. LUCOMBE, PINE & CO. have lately had an EXHIBITION OF HYACINTHS, at which several well-grown collections were entered in competition for the prizes offered by the firm. The best came from the Rev. T. J. Yarde (gardener, Mr. J. Dawe), who was followed by Mrs. Norris, Pinhoe (gardener, Mr. F. Viney), and Mr. Barnett, Tiverton (gardener, Mr. Sparkes). Mr. Dawe's Hyacinths had some handsome spikes, especially La Grandesse, which was wonderfully fine. In the second prize collection, Von Schiller, Czar Peter, and Duke of Connaught were the best. The Camellias at this nursery are now flowering very freely with many other plants.

— MESSRS. J. LAING & CO., Forest Hill, have succeeded in flowering the new CATTLEYA LAWRENCIANA, having two plants, one with a spike of three flowers, the other with two, and one bloom on another growth. The colour is good, and lip uncommonly deep (a dark purple). It may be remembered that a plant of this Cattleya was shown at South Kensington in February, but the flowers then were probably not in their best condition, as some dissatisfaction was generally expressed concerning it. The flowers are now assuming more of their true characters.

— THE WILTS HORTICULTURAL SOCIETY will hold a show at Salisbury on July 29th next, when liberal prizes will be offered in the leading classes. For twelve stove and greenhouse plants the first prize is

£15, for twelve variegated and fine-foliage stove and greenhouse plants the first prize is £13, others of smaller amount being offered in several other good classes. The Hon. Sec. is Mr. W. H. Williams, Salisbury.

— "JUVENIS" writes:—"In the Journal of the 4th inst. I was glad to find part of a letter of mine referring to HYBRIDISATION OF SWEET BRIAR, but the word 'or' is printed instead of 'and' between the words 'Sweet Briar' and 'Rosa rugosa.' I should be glad to hear whether any of the readers of the Journal have ever tried hybridising Sweet Briar with Fortune's Yellow, and whether any lovers of the Rose of long experience think any of the crosses between 'Sweet Briar' and other Roses I have mentioned worth a trial."

— THE TUNBRIDGE WELLS HORTICULTURAL SOCIETY will hold their annual Show at Tunbridge Wells on Friday, July 2nd. The annual Show of the MAIDENHEAD HORTICULTURAL SOCIETY is fixed for Thursday, August 19th, 1886.

— THE OFFICIAL REPORT OF THE ORCHID CONFERENCE held by the Royal Horticultural Society at South Kensington in May last year is now issued, forming the first portion of vol. vii. of the Society's Journal. It comprises 155 pages, giving a full report of the papers read at the Conference, the discussion, and the exhibition, the greater portion of which has already appeared in these pages and elsewhere. A horticultural report on the plants exhibited is contributed by Mr. F. W. Burbidge; and Mr. H. N. Ridley has a chapter devoted to the botanical consideration of the Orchids shown, both of which contain some interesting matter. Though somewhat late in appearing, the Report will be welcomed by many persons as giving all the particulars concerning the Conference brought together in a convenient form. It is, however, regrettable that more care has not been exercised in the revision, especially of the horticultural portion.

— WE are glad to observe that the remarkably successful SHROPSHIRE FLORAL AND HORTICULTURAL SOCIETY continues its prosperous career. The receipts for 1885 were upwards of £2250, the largest since the formation of the Society. The profits realised during the year exceeded £500, and the balance in hand at the present time is £725 10s. 4d. The Spring Show for the present year will be held on April 1st, and the Summer Show on August 18th and 19th. The schedules are comprehensive, fifty-two classes being provided for the former Show and 145 for the latter, £60 being offered in one class for stove and greenhouse plants.

— A VARIEGATA FICUS REPENS in the Cambridge Botanic Gardens, Massachusetts, is thus described: "It is beautifully variegated with white; not a dirty white as often seen in variegated-leaved plants, but a clear striking white. About half the foliage was white, giving it sufficient to make it attractive. For decorative purposes this will make a suitable plant; either grown into large specimens neatly trained, or grown in small pots, it can be kept in a compact bushy form, and will answer the same purpose some of the Selaginellas are now used for. With sufficient to cover the back wall of a fernery or Orchid house, what a beautiful object it would make. It appears to grow just as strong as Ficus repens, from which it is a sport."

— WE regret to have to announce the death of MR. ROBERT PRESTON KER of Liverpool, a nurseryman well known and much respected in the district, and by all who knew him. He was born at Hassendeanburn, Hawick, on July 21st, 1816, and was therefore in his seventieth year at the time of his death, which took place on March 4th. Under his management the business grew to be one of the most important in the north of England, and has been particularly noted in recent years for the handsome Crotons shown at the leading exhibitions.

— AMONGST many vegetable growers who read this Journal we may include a few vegetarians, to whom the following note from a professional musician will be interesting:—"I speak from an eight-year's experience as a vegetarian, adopted at the outset from motives of economy, to enable me to prosecute my studies in a most trying profession—viz., that of an 'English Musical Artist,' my day's work during the earlier years of my professional career regularly commencing within twenty minutes of rising at 4.30 A.M., and continuing, with necessary intervals for meals, for nine, ten, and sometimes twelve hours and more. This I have been enabled to accomplish without a day's illness, one or two slight accidents excepted, and ailments to which before the adoption of my vegetarian régime I was invariably subject are now strangers indeed. The

munificent sum of 5d. per day for three meals has sufficed to keep me in perfect health and thoroughly fit me for the duties of life. This matter affects the really provident poor especially, although even those whose lines have fallen in more pleasant places may well inquire if the vegetarian diet be not worth a thought in connection with the lengthy doctor's bills they are annually called upon to discharge."

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 17th inst., at 7 P.M., the following paper will be read:—"Brief Historical Account of the Barometer," by William Ellis, F.R.A.S., President. After the reading of this paper the meeting will be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of barometers, and of such new instruments as have been invented and first constructed since the last Exhibition. The Exhibition will, at the request of the Secretary of the Institution of Civil Engineers, be open in readiness for their meeting on Tuesday evening the 16th inst.

— THE TAUNTON AND DISTRICT GARDENERS' ASSOCIATION will hold a Chrysanthemum, Primula, and Fruit Show in the London Hotel Assembly Rooms, Taunton, on Thursday, November 18th, seventy classes being provided, in some of which substantial prizes are offered, as, for instance, in the class for thirty-six Chrysanthemum blooms, eighteen Japanese, and eighteen incurved, for which £5, £3, and £1 10s. are the first, second, and third prizes. The Hon. Sec. is Mr. R. H. Poynter.
